USE OF SPECIFICATION - TERMS, CONDITIONS & NOTICES

The material in this document details an Object Management Group specification in accordance with the terms, conditions and notices set forth below. This document does not represent a commitment to implement any portion of this specification in any company's products. The information contained in this document is subject to change without notice.

LICENSES

The companies listed above have granted to the Object Management Group, Inc. (OMG) a nonexclusive, royalty-free, paid up, worldwide license to copy and distribute this document and to modify this document and distribute copies of the modified version. Each of the copyright holders listed above has agreed that no person shall be deemed to have infringed the copyright in the included material of any such copyright holder by reason of having used the specification set forth herein or having conformed any computer software to the specification.

Subject to all of the terms and conditions below, the owners of the copyright in this specification hereby grant you a fully-paid up, non-exclusive, nontransferable, perpetual, worldwide license (without the right to sublicense), to use this specification to create and distribute software and special purpose specifications that are based upon this specification, and to use, copy, and distribute this specification as provided under the Copyright Act; provided that: (1) both the copyright notice identified above and this permission notice appear on any copies of this specification; (2) the use of the specifications is for informational purposes and will not be copied or posted on any network computer or broadcast in any media and will not be otherwise resold or transferred for commercial purposes; and (3) no modifications are made to this specification. This limited permission automatically terminates without notice if you breach any of these terms or conditions. Upon termination, you will destroy immediately any copies of the specifications in your possession or control.

PATENTS

The attention of adopters is directed to the possibility that compliance with or adoption of OMG specifications may require use of an invention covered by patent rights. OMG shall not be responsible for identifying patents for which a license may be required by any OMG specification, or for conducting legal inquiries into the legal validity or scope of those patents that are brought to its attention. OMG specifications are prospective and advisory only. Prospective users are responsible for protecting themselves against liability for infringement of patents.

GENERAL USE RESTRICTIONS

Any unauthorized use of this specification may violate copyright laws, trademark laws, and communications regulations and statutes. This document contains information which is protected by copyright. All Rights Reserved. No part of this work covered by copyright herein may be reproduced or used in any form or by any means--graphic, electronic, or mechanical, including photocopying, recording, taping, or information storage and retrieval systems--without permission of the copyright owner.

DISCLAIMER OF WARRANTY

WHILE THIS PUBLICATION IS BELIEVED TO BE ACCURATE, IT IS PROVIDED "AS IS" AND MAY CONTAIN ERRORS OR MISPRINTS. THE OBJECT MANAGEMENT GROUP AND THE COMPANIES LISTED ABOVE MAKE NO WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, WITH REGARD TO THIS PUBLICATION, INCLUDING BUT NOT LIMITED TO ANY WARRANTY OF TITLE OR OWNERSHIP, IMPLIED WARRANTY OF MERCHANTABILITY OR WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE OR USE. IN NO EVENT SHALL THE OBJECT MANAGEMENT GROUP OR ANY OF THE COMPANIES LISTED ABOVE BE LIABLE FOR ERRORS CONTAINED HEREIN OR FOR DIRECT, INDIRECT, INCIDENTAL, SPECIAL, CONSEQUENTIAL, RELIANCE OR COVER DAMAGES, INCLUDING LOSS OF PROFITS, REVENUE, DATA OR USE, INCURRED BY ANY USER OR ANY THIRD PARTY IN CONNECTION WITH THE FURNISHING, PERFORMANCE, OR USE OF THIS MATERIAL, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

The entire risk as to the quality and performance of software developed using this specification is borne by you. This disclaimer of warranty constitutes an essential part of the license granted to you to use this specification.

RESTRICTED RIGHTS LEGEND

Use, duplication or disclosure by the U.S. Government is subject to the restrictions set forth in subparagraph (c) (1) (ii) of The Rights in Technical Data and Computer Software Clause at DFARS 252.227-7013 or in subparagraph (c)(1) and (2) of the Commercial Computer Software - Restricted Rights clauses at 48 C.F.R. 52.227-19 or as specified in 48 C.F.R. 227-7202-2 of the DoD F.A.R. Supplement and its successors, or as specified in 48 C.F.R. 12.212 of the Federal Acquisition Regulations and its successors, as applicable. The specification copyright owners are as indicated above and may be contacted through the Object Management Group, 140 Kendrick Street, Needham, MA 02494, U.S.A.

TRADEMARKS

MDA®, Model Driven Architecture®, UML®, UML Cube logo®, OMG Logo®, CORBA® and XMI® are registered trademarks of the Object Management Group, Inc., and Object Management Group™, OMG™, Unified Modeling Language™, Model Driven Architecture Logo™, Model Driven Architecture Diagram™, CORBA logos™, XMI Logo™, CWM™, CWM Logo™, IIOP™, MOF™, OMG Interface Definition Language (IDL)™, and SysML™ are trademarks of the Object Management Group. All other products or company names mentioned are used for identification purposes only, and may be trademarks of their respective owners.

COMPLIANCE

The copyright holders listed above acknowledge that the Object Management Group (acting itself or through its designees) is and shall at all times be the sole entity that may authorize developers, suppliers and sellers of computer software to use certification marks, trademarks or other special designations to indicate compliance with these materials.

Software developed under the terms of this license may claim compliance or conformance with this specification if and only if the software compliance is of a nature fully matching the applicable compliance points as stated in the specification. Software developed only partially matching the applicable compliance points may claim only that the software was based on this specification, but may not claim compliance or conformance with this specification. In the event that testing suites are implemented or approved by Object Management Group, Inc., software developed using this specification may claim compliance or conformance with the specification only if the software satisfactorily completes the testing suites.

OMG's Issue Reporting Procedure

All OMG specifications are subject to continuous review and improvement. As part of this process we encourage readers to report any ambiguities, inconsistencies, or inaccuracies they may find by completing the Issue Reporting Form listed on the main web page <http://www.omg.org>, under Documents, Report a Bug/Issue (<http://www.omg.org/technology/agreement.htm>).

Preface

About the Object Management Group

OMG

Founded in 1989, the Object Management Group, Inc. (OMG) is an open membership, not-for-profit computer industry standards consortium that produces and maintains computer industry specifications for interoperable, portable and reusable enterprise applications in distributed, heterogeneous environments. Membership includes Information Technology vendors, end users, government agencies and academia.

OMG member companies write, adopt, and maintain its specifications following a mature, open process. OMG's specifications implement the Model Driven Architecture® (MDA®), maximizing ROI through a full-lifecycle approach to enterprise integration that covers multiple operating systems, programming languages, middleware and networking infrastructures, and software development environments. OMG's specifications include: UML® (Unified Modeling Language™); CORBA® (Common Object Request Broker Architecture); CWM™ (Common Warehouse Metamodel); and industry-specific standards for dozens of vertical markets.

More information on the OMG is available at <http://www.omg.org/>.

OMG Specifications

As noted, OMG specifications address middleware, modeling and vertical domain frameworks. A catalog of all OMG Specifications is available from the OMG website at:

http://www.omg.org/technology/documents/spec_catalog.htm

Specifications within the Catalog are organized by the following categories:

OMG Modeling Specifications

- UML
- MOF
- XMI
- CWM
- Profile specifications.

OMG Middleware Specifications

- CORBA/IIOP
- IDL/Language Mappings
- Specialized CORBA specifications
- CORBA Component Model (CCM).

Platform Specific Model and Interface Specifications

- CORBAservices

- CORBA facilities
- OMG Domain specifications
- OMG Embedded Intelligence specifications
- OMG Security specifications.

All of OMG's formal specifications may be downloaded without charge from our website. (Products implementing OMG specifications are available from individual suppliers.) Copies of specifications, available in PostScript and PDF format, may be obtained from the Specifications Catalog cited above or by contacting the Object Management Group, Inc. (as of January 16, 2006) at:

OMG Headquarters
140 Kendrick Street
Building A, Suite 300
Needham, MA 02494
USA
Tel: +1-781-444-0404
Fax: +1-781-444-0320
Email: pubs@omg.org

Certain OMG specifications are also available as ISO standards. Please consult <http://www.iso.org>

Typographical Conventions

The type styles shown below are used in this document to distinguish programming statements from ordinary English. However, these conventions are not used in tables or section headings where no distinction is necessary.

Times/Times New Roman - 10 pt.: Standard body text

Helvetica/Arial - 10 pt. Bold: OMG Interface Definition Language (OMG IDL) and syntax elements.

Courier - 10 pt. Bold: Programming language elements.

Helvetica/Arial - 10 pt: Exceptions

Note – Terms that appear in *italics* are defined in the glossary. Italic text also represents the name of a document, specification, or other publication.

Issues

The reader is encouraged to report any technical or editing issues/problems with this specification to <http://www.omg.org/technology/agreement.htm>.

1 Scope

1.1 Introduction

This specification of a UML™ profile adds capabilities to UML for model-driven development of Real Time and Embedded Systems (RTES). This extension, called the UML profile for MARTE (in short MARTE for Modeling and Analysis of Real-Time and Embedded systems), provides support for specification, design, and verification/validation stages. This new profile is intended to replace the existing UML Profile for Schedulability, Performance and Time (formal/03-09-01).

MARTE consists in defining foundations for model-based description of real time and embedded systems. These core concepts are then refined for both modeling and analyzing concerns. Modeling parts provides support required from specification to detailed design of real-time and embedded characteristics of systems. MARTE concerns also model-based analysis. In this sense, the intent is not to define new techniques for analyzing real-time and embedded systems, but to support them. Hence, it provides facilities to annotate models with information required to perform specific analysis. Especially, MARTE focuses on performance and schedulability analysis. But, it defines also a general analysis framework which intends to refine/specialize any other kind of analysis.

Among others, the benefits of using this profile are thus:

- Providing a common way of modeling both hardware and software aspects of a RTES in order to improve communication between developers.
- Enabling interoperability between development tools used for specification, design, verification, code generation, etc.
- Fostering the construction of models that may be used to make quantitative predictions regarding real-time and embedded features of systems taking into account both hardware and software characteristics.

2 Conformance

2.1 Overview

The range of applications and areas of knowledge that are inside the scope of this specification is largely broader than the current usage of traditional tools in the real-time and embedded systems market. Though all of them are related from the system perspective and will benefit from having a common place for notations, vocabulary, and semantics inside MARTE, it is a fact that a number of different specialized actors are involved. Consequently, the tools that are currently in the market, which are those expected to evolve to support this specification, have different users and specific target applications sub-domains. For this reason, and in order to ease its adoption process, this specification defines a modular approach for conformance. This is similar to the UML compliance strategy, but in this case the compliance points are not defined as stratified horizontal layers. Here they are defined as Compliance Cases, whose constitutions depend closely on the expected use cases of the specification.

Though it is recognized that the ability to exchange models between tools is extremely important, this is not compromised in this approach since interchange is only deemed useful between tools for similar and/or complementary purposes. When such purposes are similar, the exchanging tools will likely satisfy the same conformance cases. If they are complementary, model transformations and/or a broader scope of compliance cases will be required at least in one of the tools involved.

2.2 Extension Units and Features

In order to properly identify the elements of MARTE that will be required in each compliance case, the following definition is made:

EXTENSION UNITS: These are the concrete separated UML profiles or Model Libraries in which the language extensions that MARTE proposes are packaged. Some of them may require others to be complete or meaningful. Extension Units play the role of language units and/or individual meta-model packages as they are used in the definition of conformance in UML.

The Extension Units defined in this specification are listed in the following table.

Table 2.1 - Extension Units Defined

Acronym	Name, description	Section(s)
NFP	Non-Functional Properties	Section 8
Time	Enhanced Time Modeling	Section 9
GRM	Generic Resource Modeling	Section 10
Alloc	Allocation Modeling	Section 11
GCM	Generic Component Model	Section 12
HLAM	High-Level Application Modeling	Section 13
SRM	Software Resource Modeling	Section 14.1
HRM	Hardware Resource Modeling	Section 14.2
RTM	Real-Time objects Modeling (RTE MoCC)	Section 13
GQAM	Generic quantitative Analysis Modeling	Section 15
SAM	Schedulability Analysis Modeling	Section 16
PAM	Performance Analysis Modeling	Section 17
VSL	Value Specification Language	Annex B
CHF	Clock Handling Facilities	Annex C
RSM	Repetitive Structure Modeling	Annex E

2.3 Conformance of MARTE with UML

For the many of the extension units considered the Level 2 of conformance with UML may be sufficient. Though there are some extension for which several language units in Level 3 of conformance with UML are necessary, in particular Templates.

2.4 Conformance with MARTE

Tools vendors and MARTE implementers require a set of conformance definitions that allows them to better target their particular users needs without having to implement the complete MARTE Specification.

The target usages of the profile (its use cases and/or the actors involved) are good conceptual entities to look for groups of Extension Units that may lead to useful compliance definitions.

2.4.1 Compliance Cases

Considering the Use cases of this specification, (described in section 6,), the compliance cases defined are:

- Software Modeling
 - Constructs for modeling real-time and embedded (RTE) software applications and its non functional properties (NFP).
- Hardware Modeling
 - Constructs for modeling the high level hardware aspects of RTE systems, including its NFP.
- System Architecting
 - It includes both Software Modeling and Hardware Modeling compliance cases mentioned before, plus the allocation extension units.
- Performance Analysis
 - It includes the extension units necessary to address the performance evaluation of RTES
- Schedulability Analysis
 - It includes the extension units necessary to address the schedulability analysis of RTES
- Infrastructure Provider
 - It includes the extension units necessary to address the definition and/or usage of platform specific services (like OS services for example). This may be used to create RTOS services model libraries, as well as to specify the services required to a platform in order to support higher level RT design methodologies.
- Methodologist
 - Tools conforming to this compliance case are expected to support all the extension units required for the other compliance cases, which in practice means to support all the mandatory features of MARTE.

In order to manage complexity and speed up the adoption process, Compliance Cases are defined at two compliance levels: *Base* and *Full*. Each level indicates a concrete set of extension units that are consider as mandatory at that level. The Base level is defined as a subset of the Full level. Extension units that are included in the Full level, but are not in the Base level, are considered as optional at the Base level.

2.4.2 Extension Units in each compliance case

The Extension Units that must be supported in each Compliance Cases are assigned as depicted in the next table:

Table 7.2 - Extension Units that must be supported in each Compliance Case

CASE	Level	GRM	NFP	VSL	Time	CHF	SRM	HRM	GCM	Alloc	HLAM	GQAM	PAM	SAM	RSM
Software	Base	X	X		X						X				
	Full			X		X	X		X						
Hardware	Base	X	X		X			X							
	Full			X		X			X	X					X
System	Base	X	X		X					X	X				
	Full			X		X	X	X	X						X
Performance	Base	X	X		X							X	X		
	Full			X		X									
Schedulability	Base	X	X		X							X		X	
	Full			X		X									
Infrastructure	Base	X	X		X		X								
	Full			X		X				X	X				
Methodologist	Base	X	X		X			X			X	X			
	Full			X		X	X		X	X			X	X	X

2.4.3 Special additional compliance case and extension units

Tools that wish to serve AADL users should implement Section A.3 in Annex A of this specification.

3 Normative References

The following normative documents contain provisions which, through reference in this text, constitute provisions of this specification. Refer to the OMG site for subsequent amendments to, or revisions of any of these publications:

- UML 2.1.2 Superstructure Specification (OMG document number formal/2007-11-02)
- UML 2.1.2 Infrastructure Specification (OMG document number formal/2007-11-04)
- XMI 2.1 Specification (OMG document number formal/2005-09-01)

4 Terms and Definitions

There are no formal definitions in this specification that are taken from other documents.

5 Symbols

Acronym	Meaning
AADL	Architecture Analysis and Design Language
AHB	AMBA High-performance Bus
AMBA	Advanced Microcontroller Bus Architecture
ARM	Advanced RISC Machines
CAN	Controller Area Network
CCM	Corba Component Model
CORBA	Common Object Request Broker Architecture
CPU	Central Processing Unit
DMA	Direct Memory Access
DPRAM	Double-Port RAM
DRAM	Dynamic Random Access Memory
EAST-ADL2	EAST Architecture Description Language 2
EDF	Earliest Deadline First
EQN	Extended Queueing Network
FIFO	First In First Out
GQAM	Generic Quantitative Analysis Modeling
GRM	Generic Resource Modeling
GUI	Graphical User Interface
LQN	Layered Queueing Network
Lw-CCM	Lightweight CCM
MARTE	UML profile for Modeling and Analysis of Real-Time and Embedded systems
MDA	Model-Driven Architecture
NFP	Non-Functional Properties modeling
OCL	Object Constraint Language
OS	Operating System
PAM	Performance Analysis Modeling
QN	Queueing Network
QoS	Quality of Service
QoS&FT	UML Profile for Quality of Service and Fault Tolerance specification
RISC	Reduced Instruction-Set Computer
RMA	Rate Monotonic Analysis
RSM	Repetitive Structure Modeling
RTOS	Real-Time Operating System
SAM	Schedulability Analysis Modeling
SI	Système International
SPT	UML Profile for Schedulability, Performance and Time specification
SysML	Systems Modeling Language
TCP	Transmission Control Protocol
TPC-W	Transaction Processing Council Web benchmark
TVL	Tag Value Language
UML	Unified Modeling Language
VSL	Value Specification Language
WCET	Worst Case Execution Time

6 Additional Information

6.1 Scope of OMG RT/E related standards

The MARTE profile, which replaces the current profile for Schedulability, Performance, and Time, is one of a group of related OMG specifications (Figure 6.1). The most obvious of these is the UML 2 Superstructure specification, which is the basis for any UML profile. It also uses the OCL 2.0 specification for all constraints specified in OCL.

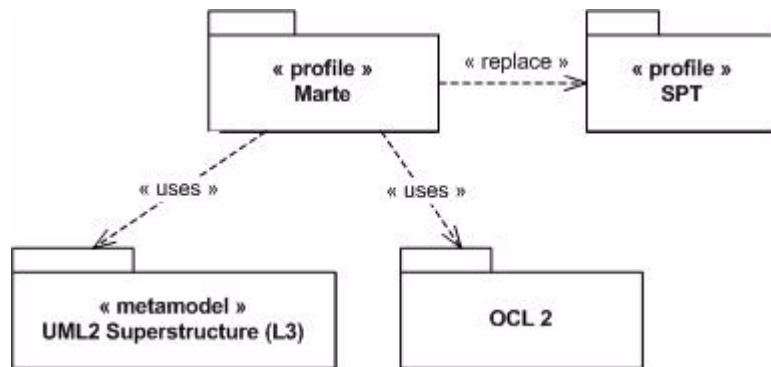

Figure 6.1 - Informal description of the MARTE dependencies with other OMG standards

Note that the Superstructure is dependent on UML compliance level 3 (L3), which is the complete UML metamodel.

In addition, MARTE is related to the following other OMG specifications:

- The UML profile for Modeling Quality of Service and Fault Tolerance Characteristics and Mechanisms. This specification provides, among other things, a generic metamodel for defining different qualities of service and is used for specifying any such characteristics defined in the MARTE profile.
- The UML profile for Systems Engineering (SysML), which deals with many of the same areas, such as the modeling of platforms and their constituent elements (hardware resources) and the allocation of software to platforms (i.e., deployment). In areas where there is conceptual overlap, MARTE is either reuses the corresponding SysML stereotypes, or defines elements that are conceptually and terminologically aligned with SysML.
- The Executable UML Foundation specification (currently in progress) defines, among other things, a model of causality for UML that is at the core of various scenario-based analysis methods (such as performance and schedulability analyses). The MARTE causality model must be fully consistent with the model specified in the Executable UML Foundation spec.
- The RTCORBA and CCM specifications address issues related to software execution platforms, real-time constraints, composition mechanisms, etc. i.e. issues that are all in the scope of the MARTE specification. All these computing platforms may be then considered as specific resources for executing MARTE model-based application.

The following OMG specifications deal with similar subject matter but are not considered relevant to this submission:

- The UML for SoC profile.
- The EDOC UML profile.

6.2 Rationale and general principles

Since the adoption of the UML standard and its new advanced release UML2, this modeling language has been used for development of a large number of time-critical and resource-critical systems (a significant number of these can be found in the various books, papers, and reports listed in the bibliography at the end of this specification). Based on this experience, a consensus has emerged that, while a useful tool, UML is lacking in some key areas that are of particular concern to real-time and embedded system designers and developers. In particular, it was noticed that first the lack of a quantifiable notion of time and resources was an impediment to its broader use in the real-time and embedded domain. Second, the need for rigorous semantics definition is also a mandatory requirement for a widespread usage of the UML for RT/E systems development.

Fortunately, and contrary to an often expressed opinion, it was discovered that UML had all the requisite mechanisms for addressing these issues, in particular through its extensibility faculties. This made the job much easier, since it was unnecessary to add new fundamental modeling concepts to UML – so-called “heavyweight” extensions. Rather, the work being done in the specification consisted in defining a standard way of using these capabilities to represent concepts and practices from the real-time and embedded domain.

6.2.1 Real-time and embedded domain

The main intent of this section is to describe the domain of interest for this current profile; i.e. the real-time and embedded domain. There is no general consensus about the definition of both real-time and embedded terms. So, it is not straight forward to define this domain. Nevertheless, it is possible to give some general descriptions of five main sub categories included in the RT/E domain category and representative of most of RT/E systems.

Embedded domain

Embedded systems are generally defined as interconnected devices that contain software and hardware (mainly electronics based) parts, but which are not computers in the classic sense. Embedded systems are computer-based systems that are deployed into an environment (part of the physical world) with which they interact.

Embedded systems development implies designing a system in which resources are usually limited, and which may need to run without manual intervention. So all errors need to be handled. As the resources are constrained (in memory size, power consumption, *etc.*) the design of embedded systems requires optimization.

The designed system will be embedded in a real application, either software or hardware. Therefore, the produced code must be easily interfaced with a software environment such as a real-time operating system (RTOS), middleware, a micro-controller or onto specific hardware (e.g. ASIC, FPGA).

Embedded systems distinguish themselves especially by following specific characteristics: heterogeneity (hardware / software), distribution (on potential multiple and heterogeneous hardware resources), ability to react (supervision, user interfaces modes), criticality, real-time and consumption constraints.

Reactive domain

Systems are generally tagged as “reactive” to stress the fact that they are meant to react to information inputs coming from some environment; The main goal of such reactive systems is actually to control, supervise, or simply collaborate or interact with this environment. Of course such systems may perform heavy data computation, but this aspect is played down and abstracted somehow in the system description.

The behavior of reactive systems usually consists of reaction cycles: first, input events are gathered from the environment (through sensors); second, a reaction is computed and decided upon; third, the proper outputs are emitted back in a timely manner in response to environment stimuli through actuators for example. The reactions may depend on a local or global state, defining the current mode of operation of the reactive system.

Reactive systems can be found in transportation (automotive, aircrafts), factory automation, in hardware/software controllers, in various embedded electronic appliances, including mobile communications.

Control/Command domain

Applications for control/command domain are usually dedicated to manage the execution of a process or object of the physical world. The command synthesis matches the production of commands toward actuators from a given request.

A request is generated after measures have been done on one or several sensors. A measure is packaged (i.e. processing the signal coming from the sensor) and then managed (i.e. taking into account the process state) in order to build the corresponding request. From a given request, it is possible to distinguish three kinds of command synthesis: (1) the regulating or the request is fixed; (2) serving that means the adaptation of a command following the order variations; (3) the trajectory monitoring in case of variable request.

The command synthesis may be achieved either in open loop or in closed loop mode. The command synthesis in open loop mode consists in designing a function that depends on the request values and parameters of the actuators. The command synthesis in closed loop mode is relying on an additional measure requiring to evaluate the level at which the request is considered and to adjust the command if needed.

Moreover, real case studies demonstrate that, in addition to the usual functions for command synthesis and measuring, it is necessary to have user information functions (via a specific API or network) and trace functions.

Systems dedicated to process control consist of three main activities: measuring, command synthesis and information output. Three components involved in the development of control/command systems may be also identified: Sensors (buttons, serial input devices, etc.) related to measuring activities; Actuators (motors, printers, etc.) related to command synthesis in open and closed loop; and output devices (e.g. screen, files, networks, etc.) related to information output.

Intensive data flow computation domain

Intensive data flow computation is mainly encountered in signal processing, image processing and mobile devices. A common scenario is a radio signal tuned by a receiver, filtered, and decoded. These different stages require intensive data computation to be performed, possibly in parallel, with the help of several computation units.

Many signal and image processing applications follow an organization in two high level stages: systematic signal processing and intensive data processing.

The systematic signal processing is the very first part of a signal processing application. It mainly consists of a chain of filters and regular processing applied on the input signals independently of the signal values. It results in a characterization of the input signals with values of interest.

The intensive data processing is the second part of a signal processing application. It applies irregular computations on the values issued by the systematic signal processing. Those computations may depend on the signal values.

Software Defined Radio receiver is a concrete industrial example of such a domain. This emerging application is structured with front end systematic signal processing including signal digitalization, channel selection, and application of filters to eliminate interferences. The data is decoded in a second and more irregular phase (synchronization, signal demodulation, etc.).

Intensive data-flow computation is an important class of embedded applications requiring hardware architectures description. It requires mainly being able to express potential parallel processing of data and parallel hardware architectures, preferably in simple ways that allow for factorization of repeated elements.

Best-effort service domain

Real-time systems sometimes include elements which do not deliver services in a totally safe or time-constrained way (such as web application servers in an IP telephony system). These systems nonetheless have properties (delay distribution, probability of failure of a service) which need to be understood.

Best-effort services supply one or more responses as data, to a request. They often make subsidiary requests to other services, particularly to data services (databases, caches, file servers, disk storage). Best-effort services are not distinguishable from systems which are not primarily designated "real-time" systems.

To a certain extent most computer systems have some aspect of requirements for real-time responses, which are affected by system resources. This profile provides some capabilities for describing and analyzing those real-time aspects of any system.

6.2.2 Guiding principles

This section aims in defining what have been the main guiding principles used to write this specification. The main guiding principles are then as follows:

- The profile should support independent modeling of both software or hardware parts of RT/E systems and the relationships between them.
- The profile has to provide modeling constructs covering the development process of RT/E systems. Such features may be categorized into qualitative (parallelism, synchronization, communication) or quantitative (deadline, periodicity). The profile must provide high-level modeling constructs for specification purposes, for example, but also low-level construct for implementation purposes.
- As much as possible, modelers should not be hindered in the way they use UML to represent their systems just to be able to do model analysis. That is, rather than enforcing a specific approach or modeling style for real-time systems, the profile should allow modelers to choose the style and modeling constructs that they feel are the best fit to their needs of the moment.
- Modelers should be able to take advantage of different types of model analysis techniques without requiring a deep understanding of the inner workings of those techniques. The steep learning curve behind many of the current model analysis methods has been one of the major impediments to their adoption.
- The profile must support all the current mainstream real-time technologies, design paradigms, and model analysis techniques. However, it should also be fully open to new developments in all of these areas.
- It must foster construction of UML models that can be used to make quantitative and partitioning predictions and analysis regarding hardware and software characteristics of the RT/E system. In particular, it is important to be able to perform such analyses early in the development cycle. For that, it has to be possible to analyze partial models. It should be possible to automatically construct different analysis-specific models directly from a given UML model. Such tools should be able to read the model, process it, and feed the results back to the modeler in terms of the original UML model.

6.2.3 How to use this specification

This section is aiming to describe which potential actors may use this specification and how they can do it. Of course, neither the actors nor use cases described in this section represent an exclusive set for how this specification can be used, but rather reflect on some of the ways that we expect it to be used or (in most cases) expanded.

Figure 6.2 describes a set of potential actors that may use this specification for designing RT/E systems.

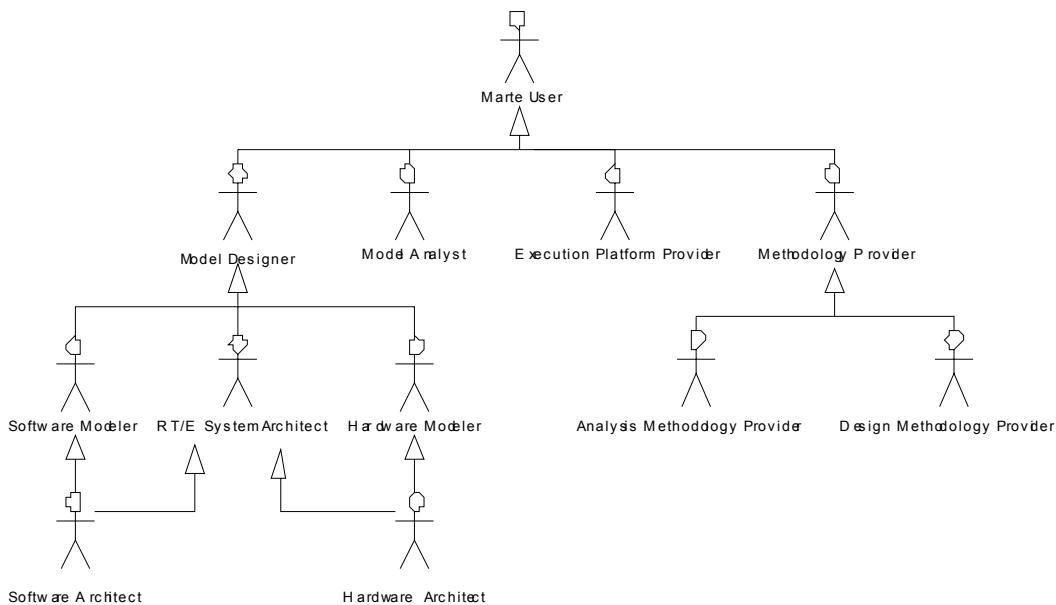

Figure 6.2 - Possible actors using the MARTE specification

- **Model Designer:** These are modelers that design models dedicated to be applied in the context of the development process of RT/E systems. Models may be used for usual specification, design or implementation stages. But models may be also used for analyzing in order to determine whether they will meet their performance and schedulability requirements.
 - **RT/E Systems Architect:** These are specific modelers concerned with the overall architecture and they usually make trade-offs between implementing functionality in hardware, software, or both.
 - **Hardware Modeler:** These are modelers specifically dedicated to hardware aspects of the RT/E systems development.
 - **Hardware Architect:** These are modelers concerned by designing hardware architecture.
 - **Software Modeler:** These are modelers specifically dedicated to software aspects of the RT/E systems development.
 - **Software Architect:** These are modelers concerned with designing software architecture.
- **Model Analyst:** These are modelers concerned with annotating system models in order to perform specific analysis methodologies.
- **Execution Platform Provider:** These are developers and vendors of run-time technologies (hardware- or/and software-based platforms) such as Real-Time CORBA, real-time operating systems and specific hardware components.

- **Methodology Provider:** These are the individuals and teams who are responsible for defining model-based methodology for RT/E domain. This category includes UML tool providers.
 - **Design Methodology Provider:** These are specialized methodology providers who are responsible for defining model-based methodology for specifying, designing or/and implementing RT/E systems.
 - **Analysis Methodology Provider:** These are specialized methodology providers who are responsible for defining model-based analysis methodology such as RMA or queuing theory, as well as technology provider such as tool vendors providing tools and processes for supporting particular model analysis methods.

Common possible usages of the MARTE profile are specified in the use case diagram depicted in Figure 6.3.

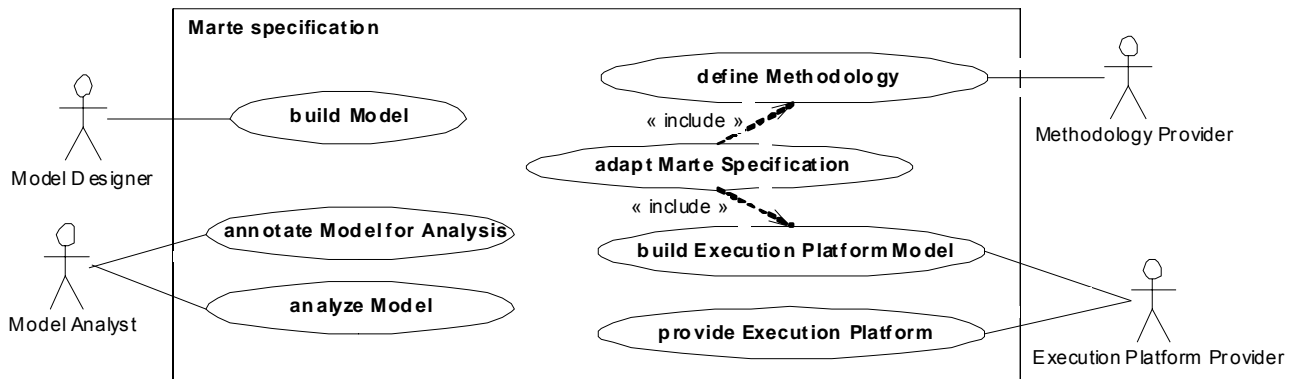

Figure 6.3 - Common use cases of the MARTE specification

Details of the use case “build Model”

- Actor: Modeler
- Description: A modeler builds a model iterating it through several stages defined in an appropriate development process. According to a given methodology (see the “define Methodology” use case), a modeler uses appropriate UML extensions or specific model libraries defined in the MARTE specification in order to describe the RT/E aspects in the model of their system.
- Deliverable: The result of this use case is a model of the user system containing all its RT/E specificities.

Details of the use case “adapt MARTE Specification”

- Actor: Methodology Provider and Execution Platform Provider
- Description: This use case consists in defining a specific MARTE sub-profile. The motivations to adapt MARTE may be either to deal with a specific domain not covered by MARTE or to define restrictions on the usage of MARTE modeling constructs. In the former case, the actor may either specialize MARTE modeling constructs in order to adapt them suitably to their needs or introduce new concepts not available in MARTE. The second way to adapt the MARTE specification is to define modeling rules in order to constraint the usage of the specification.
- Deliverable: The outcome of this use case is a definition of MARTE extension that takes the form a UML profile based on the MARTE specification. The dependencies with the MARTE profile may be merge, import or specialization.

Details of the use case “define Methodology”

- Actor: Methodology Provider

- Description: This use case consists in defining how to use the MARTE specification for a given purpose. For example, one may define a specific methodology for the design of electronic automotive systems (cf. the EAST-ADL appendix) or for avionics (see AADL appendix). One may also define model-based analysis methodology such as schedulability or performance analysis.
- Deliverable: The outcome of this use case is a model-based methodology. This latter may include a process description, a set of constraint rules and a set of required techniques that applies to the methodology. If necessary, this use case may also include the definition of an extension of the MARTE profile (include of the “extend MARTE Specification” use case).

Details of the use case “annotate Model for Analysis”

- Actor: Model Analyst
- Description: The model analyst uses appropriate MARTE extensions, as defined for example in a specific analysis methodology, in order to annotate appropriately models in order to perform a given analysis techniques.
- Deliverable: The outcome of this use case is a model annotated with MARTE extensions and ready for performing specific analysis.

Details of the use case “analyze Model”

- Actor: Model Analyst
- Description: The model analyst perform a given analysis techniques on a model. The purpose of the analysis may be varied depending of the nature of the analysis techniques used. Some examples of analysis are: schedulability or performance analyses.
- Deliverable: The outcomes of this use case are analysis results.

Details of the use case “build Execution Platform Model”

- Actor: Execution Platform Provider
- Description: This use case consists in building model of execution platform for MARTE based developments of RT/E systems.
- Deliverable: The outcome of this use case is a MARTE compatible execution platform model.

Details of the use case “provide Execution Platform”

- Actor: Execution Platform Provider
- Description: This use case consists in providing execution platform conform to a given model of platform.
- Deliverable: The outcome of this use case is an execution platform.

6.3 Approach and structure

6.3.1 Profile architecture

The profile is structured around two main concerns, one to model the features of real-time and embedded systems and the other to annotate application models so as to support analysis of system properties. These are shown by the RTEM package named “MARTE design model” in Figure 6.4, and the cluster of three packages, respectively. These two major

parts share common concerns with describing time and the use of concurrent resources, which are contained in the shared package named “MARTE foundations”. Finally the “AnalysisModeling” features are broken into a foundational generic part in the package GQAM, and two packages for specific analysis domains, as shown. These first two specific analysis domains are entirely concerned with time, however the profile structure allows for adding additional analysis domains, such as power consumption, memory use or reliability. It is the intention to encourage modular sub profiles like the two analysis packages, for such domains.

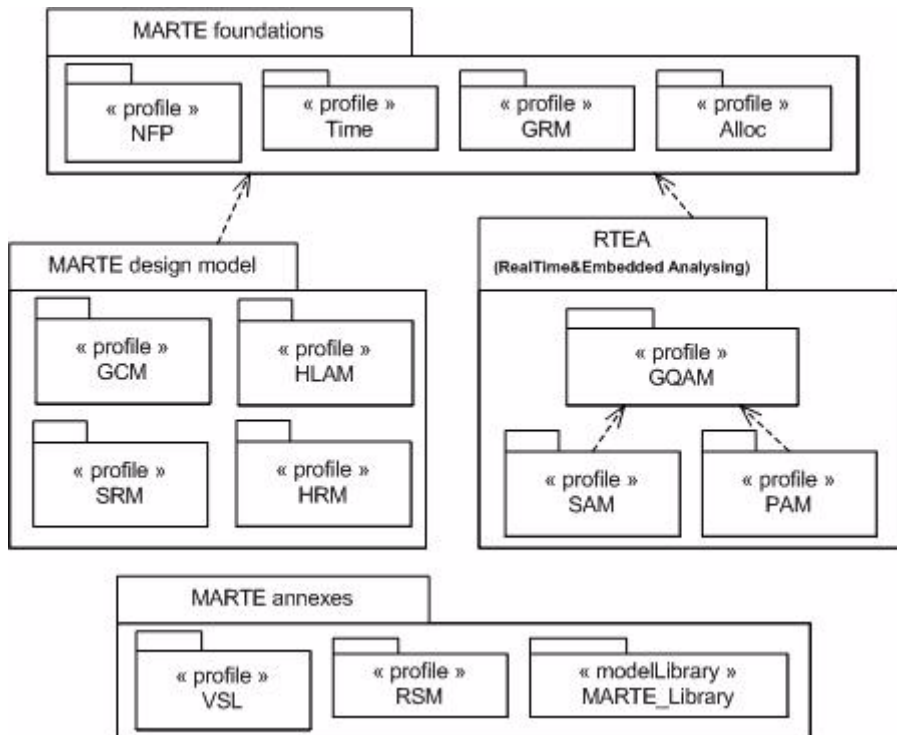

Figure 6.4 - Architecture of the MARTE Profile

6.3.2 A foundation for model driven techniques

The profile is intended to provide a foundation for applying transformations from UML models into a wide variety of analysis models. The environment for exploiting the profile would consist of a set of tools, including model transformers, as shown in Figure 6.5. Prototypes of such tool chains have been produced based on SPT.

The forward path shows the way the model is expected to be transformed via the XMI output, to a format readable by an analysis tool. The dashed line indicates a potential feedback path to re-import the analysis results into the UML diagrams.

Another feedback path clearly exists from the analysis to the modeler.

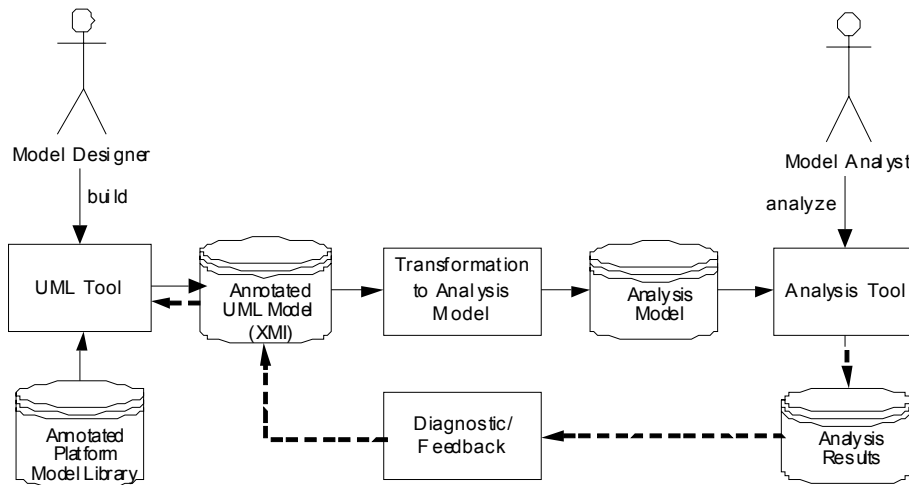

Figure 6.5 - A Tool Chain for Carrying out Analysis of a Model

6.3.3 Approach to modeling RT/E systems

Embedded systems are becoming increasingly heterogeneous. This is true of applications, which combine intensive, often heavily pipelined, data computation for signal processing, together with control mode switches and communication protocols. This is true also of execution platforms, which comprise flexible or custom-made hardware, multi-core processors, cache and bus hierarchies and so on. This is reflected in the design of such systems, which must try to fit best applications onto existing platforms, or even adjust and dimension again execution platforms for pre-existing applications. The main criteria governing this allocation of application functions to HW/SW execution resources are stringent real-time requirements, but power- and area-consumption or cost also play a role. Adequate modeling can of course be of great help with this design activity by providing the support for design and analysis. The modeling support should also encompass early global timing budget and maximal latency requirements, as well as scheduling results display expressing the explicit quality of allocation in a traceable manner.

Application modeling is based on interacting component blocks for structural aspects. As for behavior, data-intensive pipe-lined computations are generally represented with block-diagrams amenable to activity charts, while control-flow parts and communication protocols use hierarchical finite-state machines. This functionality is complemented with timing aspects, based on appropriate time/cycle descriptions (see time model section below). Application modeling is further described in chapter 9.

Execution platform modeling comprises the description of both dedicated hardware and (middleware) software layers and interconnects composing the platform. It can be described at the same level of abstraction as the application, and contains also timing information along with structural and behavioral aspects. Explicit detailed modeling can be needed in as far as the appropriate match between application and architecture is to be studied (hierarchical cache structure or Instruction Set Simulators for instance). Execution platform modeling is further described in both chapters 10 (p. 99) and 14 (p. 175).

The allocation model describes the association matching applicative functions onto execution platform resources. It is sometimes mandatory to provide timing information on this allocation link itself, rather than on its constituents, for reasons of modular abstraction (for instance one may indicate that a complex filter function can be realized at a given cost on a given specific processor, without going back to individual statements and instructions). Allocation modeling is further described in chapter 12 on page 141.

Note: allocation is here reminiscent of the similar notion in the SysML proposal.

Regular iterative constructs, that are often encountered in the embedded world to represent signal-processing applications or dedicated DSP operator blocks, or processor arrays, are best modeled using dedicated iterative model representations such as described in Annex E on page 413.

6.3.4 Approach to annotating for model analysis

Annotations use stereotypes which permit us to map model elements into the semantics of an analysis domain such as schedulability, and give values for properties which are needed in order to carry out the analysis. We may distinguish “input” properties which are needed to carry out the analysis, and “output” properties which are determined by the analysis. However the modeler may also input required values of output properties, which can be used to determine how well the system meets its requirements (another output property).

Analysis is not always simply “pass/fail”, and the particular goals of analysis are specific to its domain. Output properties to be reported may include details of how and where time and resources are consumed, in order to diagnose problems, and may include sensitivity studies to explore the importance of parameters whose values are uncertain.

6.3.5 MDA and MARTE

The MARTE profile defines precise semantics for time and resource modeling. These precise semantics allows automatic transformations of models to lower abstraction level models such as UML for SoC for hardware / software simulation or into C++ for implementation purpose.

One of the goals of this profile is to support common design flows for RT/E systems. One of these design flows is to define in different views or models the application (including functional and non functional characteristics), the hardware architecture and the allocation of the application onto the hardware architecture. Starting from this allocation model, if the semantics is precise enough, one can automate code generation for simulation at different abstraction levels or synthesis of specific hardware parts.

Another use of MDA (or MDE, “Model Driven Engineering”) with the MARTE profile is the integration of tools. Indeed, some analysis or verification tools can be coupled with the modeling tools if the semantics of the models correspond to the semantics of the analysis or verification tool. Model transformation techniques can then be used to enable this coupling.

6.4 How to read this specification

6.4.1 Structure of the document

The MARTE specification consists of five blocks of chapters:

- Block one gathers the introduction chapters (from chapter 1 to 6).
- Block two is the part I of the MARTE specification and it is intended to define the MARTE foundations. It conflates chapters 7 to 12 respectively focused on: chapter 7, Core Elements, defines the basic elements for model-based approach and specially for real-time embedded domains such as a causality model; chapter 8, Non-Functional Properties modeling, defines a common framework for annotating models with quantitative and qualitative non-functional information; chapter 9, Time modeling, defines the time as used within MARTE; chapter 10, Generic Resource Modeling, specifies how to describe at system level resource models; finally, chapter 11, Allocation modeling, defines concepts required to describe allocation concerns.

- The third block is the part II of the MARTE specification. It is intended to define the MARTE concepts for model-based design of RTES. It consists of both following chapters: chapter 12, General Component Model, introduces a general component model suitable for RTES. This component model, called GCM, is built on top of the composite structure of the UML, and it is compatible with well-known component models such as the one of SysML, CCM, AADL and EAST-ADL; chapter 13, High-Level Application Modeling, defines high-level concepts for designing qualitative and quantitative concerns of RTES (e.g., concurrency and synchronization); chapter 14, Detailed Resource Modeling, is split into two sub-sections respectively dedicated to detailed modeling of software (section 14.1, SRM, “Software Resource Modeling”) and hardware (section 14.2, HRM, “Hardware Resource Modeling”) resources.
- The fourth block is focused on model-based analysis. It does not intend to define new analysis technologies, but to define the information required for annotation models on which external analysis techniques may be applied. It consists of three chapters: chapter 15, Generic Quantitative Analysis Modeling, defines basic concept for specific analysis techniques; chapter 16, Schedulability Analysis Modeling, specializes the generic framework for performing schedulability analysis, whereas chapter 17, Performance Modeling, is the specialization for model-based performance analysis.
- The last block contains all the MARTE annexes. The main information contained within these annexes is about additional useful value specification languages provided by MARTE (Annex B and Annex C): the Value Specification Language (VDL), the Clocked Value Specification Language (CVSL) and the Clock Constraint Specification Language (CCSL). Another important added value contained is a predefined MARTE model library (Annex D). This latter annex describes predefined primitive and data types required for defining the UML profile for MARTE itself, but also useful for user models. The annex part owns also a UML extension definition (Annex E, the Repetitive Structure Modeling MARTE subprofile) intended to support specific system modeling consisting of repetitions of structural elements, interconnected via a regular connection pattern. We call this kind of structures “repetitive structures”. Finally, the annex block of MARTE owns an annex dedicated to describe the detailed semantics of each domain concept introduced within the specification (see following section which relates on how to use this Annex F).

6.4.2 Extension specification rationale and format convention

Each extension proposed by MARTE has been conflated around one main concern and detailed in separate chapters: chapter 7 to chapter 17 and Annex F. Such chapters are then organized following the same patterns. The way to define each sub-profile contained within MARTE relies on a two-stage process: a domain model specification and its underlying UML profile design.

The first stage consists in defining of the required concepts (also called domain elements) related to one specific concern (e.g., non-functional properties modelling and time modelling). The output of this stage is then called the domain model which is formalized through the definition of a meta-model and the detailed semantics descriptions of each of its elements. In order to reduce the bulk of this document, we decided to gather all these detailed descriptions within a common place, the Annex F.

The second stage of the process we adopted for MARTE aims at designing a UML profile (sections called “UML representations”). Our purpose is then to define UML extensions (i.e., mainly stereotypes, tagged values, specific notations and OCL rules) for supporting within the UML the specific concepts introduced within each MARTE domain model for supporting RTES model-based engineering.

In order to minimize the impact of the MARTE proposed extensions on the model readability, firstly we try to reduce the size of stereotype names as much as possible, but without sacrificing too much their meaning. Secondly, we decide to prefix the stereotypes only when required. A typical example was when we define a stereotype that was inherited from other stereotypes.

6.4.3 Conventions and typography

In the description of this specification, the following conventions have been used:

- While referring to stereotypes, metaclasses, metaassociations, metaattributes, etc. in the text, the exact names as they appear in the model are always used.
- No visibilities are presented in the diagrams, since all elements are public.
- If a section is not applicable, it is not included.
- Stereotype, metaclass and meta-association names: initial embedded capitals are used (e.g., ‘ModelElement’, ‘ElementReference’).
- Boolean meta-attribute names always start with ‘is’ (e.g., ‘isComposite’).
- Enumeration types always end with “Kind” (e.g., ‘DependencyKind’).
- In diagrams described in the rest of this document, the way of identifying an element external to the package being described will be its name preceded by the hierarchy of containing packages/namespaces; the root element to use for this sequence shall be the closest ancestor in the hierarchy which is common to both, the imported element, and the package being described.

6.5 Acknowledgements

- Alcatel
- ARTISAN Software Tools
- Carleton University
- Commissariat à l’Energie Atomique
- ESEO
- ENSIETA
- France Telecom
- International Business Machines
- INRIA
- INSA from Lyon
- Lockheed Martin
- MathWorks
- Mentor Graphics Corporation
- No Magic
- Software Engineering Institute (Carnegie Mellon University)
- Softeam
- Telelogic AB
- Thales
- Tri-Pacific Software
- Universidad de Cantabria

The following persons were members of the core team that designed and wrote this specification (sorted in alphabetical order): Charles André, Jean-Philippe Babau, Pierre Boulet, Irv Badr, Arnaud Cuccuru, Gérard Cristau, Jérôme Delatour, Cédric Dumoulin, Sébastien Demathieu, Robert De Simone, Huascar Espinoza, Madeleine Faugère, Sébastien Gérard, Peter Kortmann, Frédéric Mallet, Julio Medina, Alan Moore, Chokri Mraidha, Dorina Petriu, Laurent Rioux, Bran Selic, Safouan Taha, Jean-Pierre Talpin, Frédéric Thomas, Murray Woodside and Ben Watson.

In addition, the following persons contributed valuable ideas and feedback that significantly improved the content and the quality of this specification (sorted in alphabetical order): Jérôme Blanc, Joel Champeau, José María Drake, Thierry Gautier, Michael González Harbour, Jack Low, Benoît Masson, and Yves Sorel.

Part I - MARTE Foundations

This Part contains the following chapters:

- 7 - Core Elements (CoreElements)
- 8 - Non-functional Properties Modeling (NFPs)
- 9 - Time Modeling (Time)
- 10 - Generic Resource Modeling (GRM)
- 11 - Allocation Modeling (Alloc)

7 Core Elements (CoreElements)

7.1 Overview

The concepts presented in this section serve as a general basis for the description of most elements in the domain view of the rest of this specification. They are not new extensions to UML but a comprehensive set of related concepts that is useful to define those others more elaborated, which are used to build the domain models of subsequent chapters of this specification. They are split in two packages for convenience. The *Foundations* package holds the basic elements used to represent the dual descriptor-instance nature of any modeling entity. These concepts may serve to different purposes for modeling and analysis, and are the basis for structural modeling. The *Causality* package describes the basic elements necessary for behavioral modeling, and their run-time semantics. Figure 7.1 shows these packages and their relationship.

Figure 7.1 - Dependencies between packages for the CoreElements package

The Causality package is a specification of how things happen at run time. The purpose of this model is to provide a very high-level view of the *run-time semantics* for those modeling elements that are suitable for real-time and embedded systems, and will be later used when required to point out the various elements of that view that are covered and specialized in the domain models of the MARTE specification. The term “run-time” is used to refer to the execution environment. Run-time semantics are therefore specified as a mapping of modeling concepts into corresponding program execution phenomena.

This model is used as a basis for any dynamic model description associated with the MARTE profile. It captures the essentials of the cause-effect chains in the behavior of run-time instances. The model is inspired from (and hence compliant with) the Common Behavior model of the UML superstructure. But, it is more detailed and precise in certain aspects, in particular for its further use as the basis for the definition of a richer timing model, which includes the timing constraints induced by the real-time annotations. A complete model and a language for timed expressions are provided at full length in section 9. Other dedicated attribute properties for time-related concepts are also introduced further along this specification. Figure 7.2 presents the internal sub-packages of the causality model. The purpose and contents of each sub package are described in next sections.

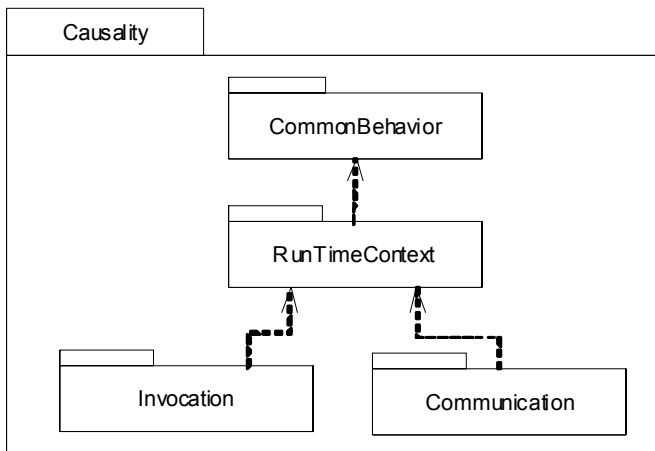

Figure 7.2 - Architecture of the Causality package

7.2 Domain view

7.2.1 The Foundations package

The domain models presented in this specification will use a consistent set of modeling elements, which in spite of being non-normative, form a large meta-model that covers all the modeling requirements imposed by the RFP.

For modeling and analysis purposes, it is fundamental to distinguish between design-time classifier elements, such as classes and types, and run-time instance elements that are created on the basis of those classifiers. All modeling elements at any level of specification will represent either one or the other of these two fundamental aspects, based on their purpose.

This basic partitioning into classifiers and instance is reflected in the diagram depicted in Figure 7.3. Any number of instances can be created from a given classifier. This latter is referred to as the type of the instance. Notice that an instance may have multiple types (which can be used either to represent different viewpoints of the model element) or a composition of partial descriptions, including multiple inheritance for example).

The concept of Instance may be in practice represented in UML not only as InstanceSpecifications but also by those other elements that are described in terms of role-based models (like UML::ConnectableElement in collaborations or internal structure diagrams, parts, ports, or roles).

Figure 7.3 - Instance and Classifier root diagram of the Foundations package

As it is described in Chapter 8, values of non-functional properties (NFP) may be annotated on any model element designated as such. In this way, further specializations of Classifiers or Instances may become kinds of AnnotatedElements. In particular, time-based analysis methods operate on annotated models that are usually described over a number of specific instances of the system. However, it is also useful to be able to associate NFP values with classifiers. In this case it simply means that such values apply by default to all instances created on the basis of those descriptors, and not that the classifier itself has that value. These default values can be further overridden in specific instance cases. But, this uniform annotation of instances requires special care and may not always be appropriate. In case of interface specifications, for example, there could be many realizations of the same interface, each with different service characteristics described by means of NFP.

For practical reasons, most concepts and modeling elements in the domain views of this specification as well as the stereotypes in the UML representation will be defined and described using the classifier root concept, but it should be noted that a corresponding instance may also exist. However, instance based elements will be defined to stress its nature, when appropriate. This semantic variation will also be taken into account in the UML views of the specification firstly to define the applicability of the required consistency rules, and secondly in the subsequent adoption of the proper semantics when the corresponding stereotype is applied to extend user defined modeling elements.

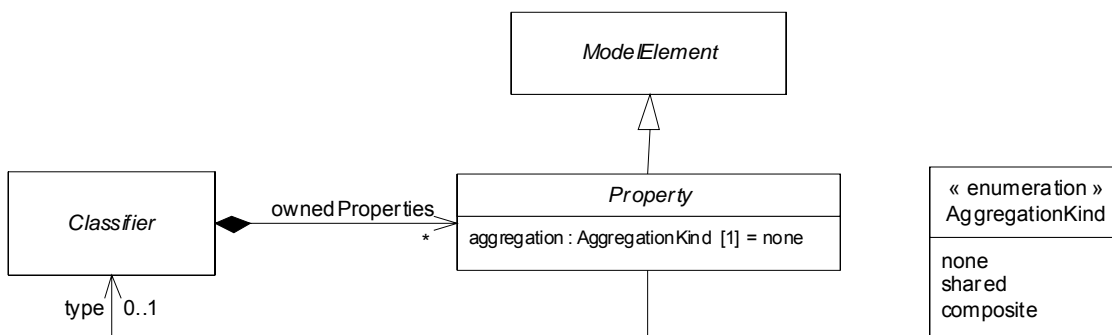

Figure 7.4 - Property diagram of the Foundations package

As the UML homonymous concept a property is a typed element that may be owned by a classifier. It has a multiplicity in terms of upper and lower bounds, an aggregation kind, and a type (as a Classifier).

7.2.2 The Causality::CommonBehavior package

This model states the relationships between classifier element models and their instances from a behavioral viewpoint. It is aligned to the UML semantics basis, in the sense that there is no disembodied behavior: all behavior emanates from the actions of structural entities. In particular since in UML a behavior is a kind of class, it is possible for a behavior to be its own structural context. For many of the UML behavioral concepts mentioned here you may find the corresponding UML2 semantics description in Chapter 13 of the OMG document ptc/06-04-02. For those that reify the UML2 concepts, analogous definitions have been extracted from that OMG document.

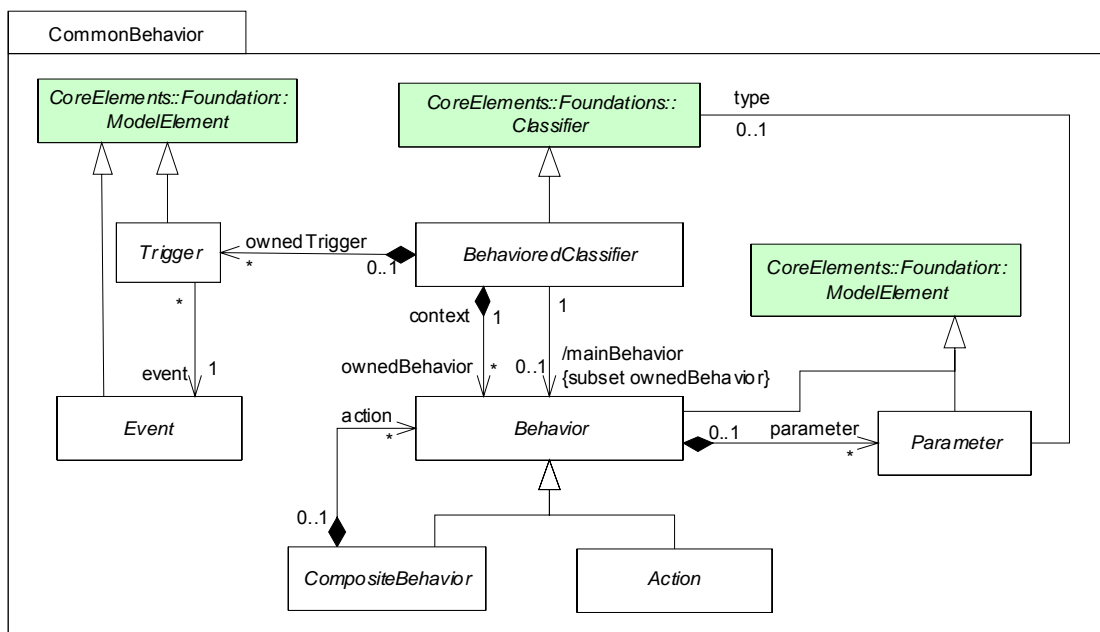

Figure 7.5 - The CommonBehavior package

A *Behavior* defines how some system or entity changes over time. From a modeling point of view, this concept defines the behavior of some classifier, specifically, a *Behavored Classifier*. A behavior captures the dynamic of its context classifier. It is a specification of how its context classifier as well as the state of the system that is in the scope of the behavior may change over time. A behavior may have *Parameters* whose values may be used for evaluating a behavior. A behavored classifier may have behavior specifications which illustrate specific scenarios of interest associated with that classifier, such as the start-up scenario. In particular, the behavior specification used to represent the behavior that starts executing when instances of that classifier are created and started is called main behavior. For many real-time concurrent systems, this can be for example the behavior that initiates the activity of a thread, which continues until the thread is terminated. Two kinds of Behavior may be defined: *CompositeBehavior* and *Action*. Action is an atomic behavior, and *CompositeBehavior* may contain other Behaviors, which in turn may be either composite or atomic.

An *Action* is the fundamental unit of behavior. An action takes a set of inputs and converts them into a set of outputs, though either or both sets may be empty. Actions are contained in behaviors, which provide their context. Behaviors provide constraints among actions to determine when they execute and what inputs they have.

An *Event* is the specification of a kind of change of state that may happen in the modeled system. Event occurrences are often generated as a result of some action either within the system or in the environment surrounding the system. Consistently with UML 2, Triggers are specification of what can cause execution of behavior (e.g., the execution of the effect activity of a transition in a state machine).

A *Trigger* specifies the event that may trigger a behavior execution as well as any constraints on the event to filter out event occurrences not of interest. Indeed, a *Trigger* is the concept that relates an Event to a Behavior that may affect any instance of the behavioral classifier.

The Timed versions of these concepts are introduced in section 9, under the name of TimedProcessing (for Actions) and TimedEvents (for Events and Triggers).

7.2.3 The Causality::RunTimeContext package

A *BehaviorExecution* is a specification of the execution of a unit of behavior or action within the instances of BehavedClassifiers. Hence, behavior executions are run-time instances of the behavior and action concepts. For this reason, in this domain model, this concept is specialized into both important concepts: *CompBehaviorExecution* and *ActionExecution*. Correspondingly, events have instances called *EventOccurrences*.

Any behavior execution is the direct consequence of the action execution of at least one instance of a classifier. A behavior execution specification describes how the states of these instances change over time. Behavior executions, as such, do not exist by their own, and they do not communicate. If a behavior execution operates on data, that data is obtained from the host instance.

In UML2, there are two kinds of behaviors at run-time, emergent behavior and executing behavior. An executing behavior is performed by an instance (its host) and is the description of the behavior of this instance. Emergent behavior execution results from the interaction of one or more participant instance.

MARTE does not highlight this difference on the nature of behaviors. Indeed, it deals only with behavior execution as the general concept to express a behavior instance. Hence, the MARTE BehaviorExecution notion corresponds to the UML2 Behavior Performance concept described in the overview section of its common behavior chapter.

On one hand, a behavior execution is thus directly caused by the invocation of a behavioral feature of an instance or by its creation. In either case, it is a consequence of the execution of an action by some related classifier instance. A behavior has access to the structural features of its host instance.

On the other hand, behavior execution may result from the interaction of various participant instances. If the participating classifier instances are parts of a larger composite classifier instance, a behavior execution can be seen as indirectly describing the behavior of the container instance also. Nevertheless, a behavior execution can result from the executing behaviors of the participant instances.

This latter form of behavior is of interest since the behavior that is to be analyzed and observed at the system level, in order to predict its timing properties, is normally described as an abstract view of the run-time emergent behavior due to the combination of the behavior executions of all its constituent parts.

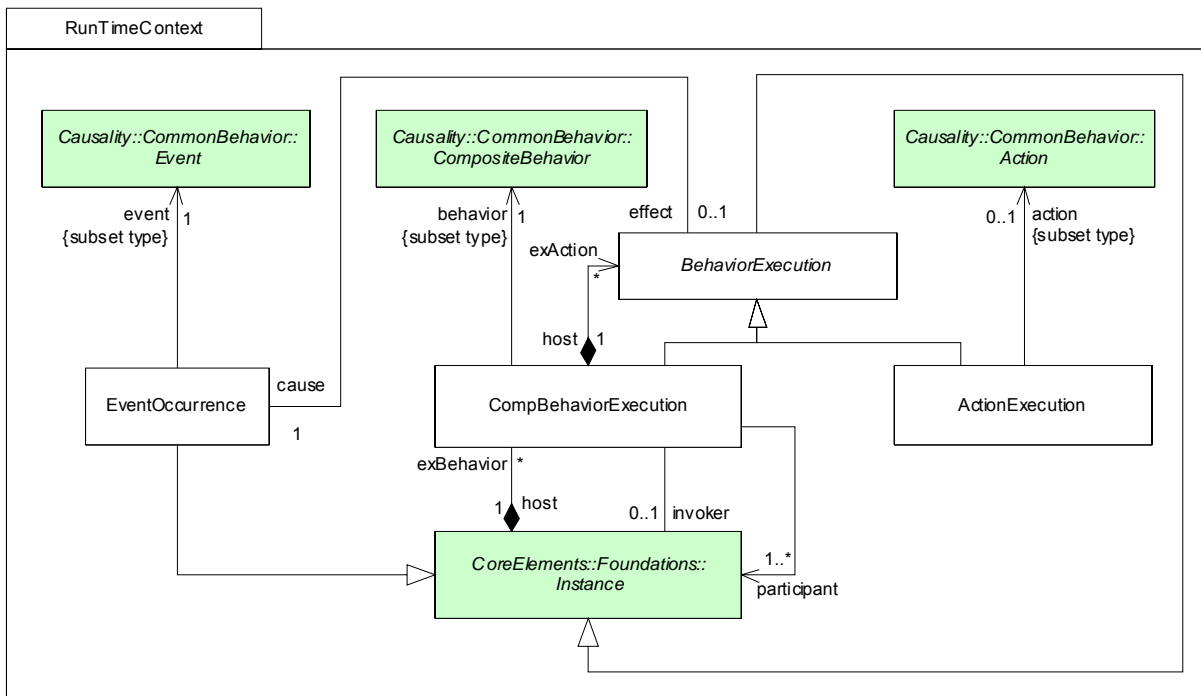

Figure 7.6 - The RunTimeContext package

There is a variety of behavior specification mechanisms supported by the UML, such as automata, activities (data-flow like description), Petri-net like graphs, informal descriptions (e.g., Use Cases), or partially-ordered sequences of event occurrences (Interactions), each corresponding to the concrete subtypes of Behavior that it provides.

This model supports not only scenario-based style for behavioral specification, by describing the observable event occurrences resulting from the execution of one possible situation of behavior execution, but it also extends the behaviors supported by the specification to state-based and activity-based approaches. The latter describe behaviors by specifying a state machine that do not describe observable event occurrences, but that would implicitly induce event occurrences. This intends to extend the domain of applicability of the MARTE profile to modeling and analysis techniques as Timed Automata, and Petri-nets.

Nevertheless, the relationship between a specified behavior and its hosting or participating instances is independent of the specification mechanism chosen. The choice of specification mechanism is one of convenience and purpose; typically, the same kind of behavior could be described by any of the different mechanisms. Note that not all behaviors can be described by each of the different specification mechanisms, because behaviors do not have the same expressive power. However, for many behaviors, the choice of specification mechanism depends on the formalism used to analyze the system.

7.2.4 The Causality::Invocation package

As shown in Figure 7.7, the execution of a behavior may be caused by an event occurrence. Events can occur from the direct invocation of a behavior through an action or from a trigger occurrence representing an indirect invocation of a behavior, such as through an operation call.

In a number of analyses, it is also useful to consider the events that occur when a behavior starts and ends its execution. A start occurrence marks the beginning of a behavior execution, while its completion is accompanied by a termination occurrence.

These and further defined concepts specialized from EventOccurrence will be considered eligible to be extended by timing annotations, though for simplicity in the domain model these annotations may be defined in the form of extensions to their common ancestor EventOccurrence.

Figure 7.7 - The Invocation package

7.2.5 The Causality::Communication Package

The Communication sub package of the Causality package adds the infrastructure to communicate between classifier instances and to invoke behaviors. The domain model in Figure 7.8 shows how a communication takes place. This domain model specifies the general semantics of communication between concurrent units.

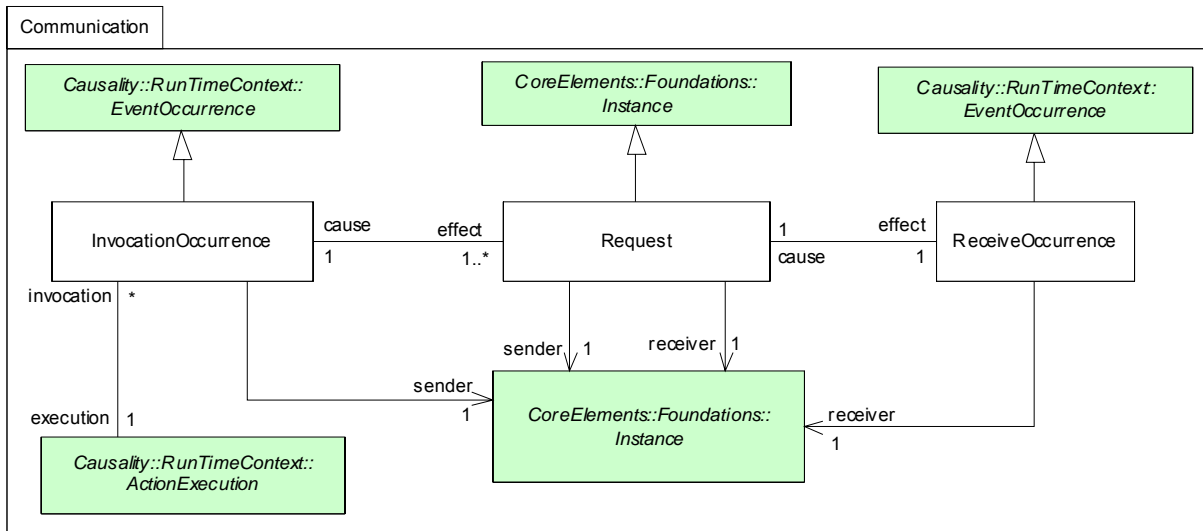

Figure 7.8 - The Communication package

In real time systems, the basic unit of logical concurrency is commonly known as a thread¹. Threads are the root of a special case of instances, usually called active, or real-time or even reactive objects. In fact, the recommended way of adding concurrency into an object model is to identify the desired concurrent units (logical or physical depending of the detail level of the model) through the application of concurrency identification strategies. Once the threads are identified, the developer may create an active object for each. According to the level of specification other forms of expressing concurrency in UML may be used, like the fork in an activity, or a state with orthogonal regions. Other objects, i.e. those which are not identified as concurrent units, are then usually called passive objects. These latter objects are then associated to the active objects via a composition or shared relationships. The role of the active object is to run when appropriate and call or delegate actions to the passive objects that it owns. Passive objects execute usually using the concurrent resource of the caller active object.

Instances respond to messages that are generated by others executing communication actions. When these messages arrive, the receivers eventually respond by executing the behavior that is matched to that message. The dispatching method by which a particular behavior is associated with a given message depends on the higher-level formalism used and is not defined here (hence, it is an open-variation semantics point of UML).

Figure 7.8 shows the general communication model. An action representing the invocation of a behavioral feature is executed by a sender instance resulting in an *InvocationOccurrence*. The invocation event may represent the sending of a signal or the call to an operation. As a result of the invocation event occurrence a *Request* is generated.

A *Request*, which fully corresponds to the Request concept of UML 2, is an instance of a communication in transit between a calling instance and a called one. In fact, a request is an instance capturing the data that was passed to the action causing the invocation event (the arguments that must match the parameters of the invoked behavioral feature);

1. It should be noted here that from the concurrency point of view, there is no distinction between threads, tasks, and processes. They all are variations of the very same concept, though they may differ in some aspects of their detailed properties (such as the context switch time and whether low-cost pointers can be used across the concurrency boundary).

information about the nature of the request (i.e., the behavioral feature that was invoked); the identities of the sender and receiver instances; as well as sufficient information about the behavior execution to enable the return of a reply from the invoked behavior, where appropriate. Eventually the request may include additional information, like a time stamp.

While each request is targeted at exactly one receiver instance and caused by exactly one sending instance, an occurrence of an invocation event may result in a number of requests being generated (as in a signal broadcast). The receiver may be the same instance that is the sender, it may be local (i.e., an instance held inside the currently executing instance, or the currently executing instance itself, or the instance owning the currently executing instance), or it may be remote. The manner of transmitting the request, the amount of time required to transmit it, the order in which the transmissions reach their receiver instances, and the path for reaching the receiver instances are to be defined and annotated by using any of the different communication mechanisms available, like rendezvous, message queuing, interrupts, etc.

Once the generated request arrives at the receiver instances, a *ReceiveOccurrence* occurs, which according to the triggers expected may subsequently launch the behaviors of the receiver instance or of any of its internal instances. Like in the Common Behaviors Domain Model of UML, two kinds of requests are determined according to the kind of invocation occurrence that caused it: the sending of a signal, and the invocation of an operation. The former is used to trigger a reaction in the receiver in an asynchronous way without a reply. The latter applies an operation to an instance, which may be synchronous or asynchronous and may require a reply from the receiver to the sender.

Observe that modeling elements like invocation occurrence and receive occurrence shown in this domain model are not explicitly represented in the specification of a system, but they are implicit in the dynamic semantics of the constructs used.

7.3 UML Representation

As stated before, this chapter does not define concrete extensions to UML offered as stereotypes to the user. Instead it collects a number of primitive modeling concepts to be used in the domain models of other chapters in this specification. Nevertheless, a certain impact on the representation of modeling elements is envisioned according to their classifier/instance dual nature.

The modeling elements defined in this specification may adopt the nature of Classifier or Instance presented here, or both. This quality of being may be of course specifically stated as part of their definition, but it may be also left to the user to be decided according to the purpose of the annotation, and the intended semantics.

In most of the cases the concepts defined in the domain view are proposed to be represented in UML by means of a stereotype extending a concrete UML modeling element. When this is the case, the Classifier or Instance intrinsic nature of the UML annotated element may lead to identify the corresponding nature, semantics, or concrete variations of the MARTE concept that is intended to be represented with the annotation. Hence, the explicit different semantics that may be defined for each MARTE modeling concept, when it is considered as an instance or as a classifier, may be inferred directly from the fundamental nature of the corresponding UML element that is annotated.

When a stereotype is applied on an instance, and provided it can be also applied on classifiers, the value of the attributes not explicitly assigned in the annotation of the instance are taken in principle from the defaults in the profile stereotype definition, but they might be overridden by those in its corresponding classifier, if it happens to be annotated with the same stereotype.

8 Non-functional Properties Modeling (NFPs)

8.1 Overview

This chapter describes both domain model and its UML representation for specifying Non-Functional Properties (NFPs). It also describes how NFPs may be attached to UML modeling elements. This sub package of the MARTE specification provides a general framework for annotating UML models with NFPs. It is especially focused on formalizing a set of modeling constructs in order to specify this kind of properties in a detailed way.

The NFP modeling framework deals with the following requirements²:

- How NFPs are to be described, and particularly what NFPs should be considered.
- How particular instances of NFPs are to be attached to UML model elements.
- How relationships between different NFPs are to be defined.
- How to express constraints on or between NFPs in order to express requirements on the system model.
- Usability of the annotations should minimize the designer efforts³.
- To provide an open modeling framework, i.e. not tailored towards specifications of a particular modeling concern or a restricted set of NFPs.

Although the UML Profile for “Modeling Quality of Service and Fault Tolerance Characteristics and Mechanisms” (QoS&FT) already defines a framework to express a similar concept to NFP, there are some reasons to define a different one in the context of this specification.

For instance, the QoS&FT profile relies on a two-step annotation process: a) derive a *Quality Model* for each application model by instantiating template classes from the QoS Catalogs and, b) annotate UML models with *QoS Constraints* and *QoS Values*, which implies catalog binding and either the creation of extra objects (instantiated from the Quality Model), or the specification of long OCL expressions. This two-step process requires too much effort for the users and may induce not readable models.

The QoS&FT profile provides a flexible mechanism to store pre-defined *QoS Characteristics*. It supports declaring the most common QoS characteristics for different application domains by means of QoS Catalogs. A particular QoS Catalog may contain qualifiers of QoS properties including statistical qualifiers and measurement units. At the level of QoS value specifications, however, QoS&FT ignores some important attributes such as measurement sources, precision, and time expressions. These properties are required for the domain of MARTE and are therefore supported by the NFPs introduced in this specification and the Value Specification Language (VSL) defined in Annex B.

In general, the term Quality of Service (QoS) is the aptitude of a service for providing a quality level to the different demands of its clients. In the computer systems domain, the term QoS is frequently associated specifically with network issues, such as throughput and bandwidth (and in conjunction with multimedia applications). But it has more recently begun to be applied to NFPs of more general services. There is still no common consensus about the concepts of NFP and

-
2. A list of compliance with the MARTE RFP have been included in Annex. It also relates how this document deals with the initial MARTE RFP requirements.
 3. One of the major constraints that drove the definition of this specification has been to minimize the required efforts to apply the profile. But since our purpose was to enrich UML with capacities to describe formally and efficiently the real-time and embedded features of a system, applying the profile hence requires some additional effort with regard to a common usage of the UML.

QoS. Anyhow, the NFPs considered here have a larger extent than only quality levels. NFPs may describe the internals and externals of the system, and some of them directly relate to the users of resource services and their QoS perception and others not.

Besides, the UML profile for “Schedulability, Performance, and Time Specification” (SPT) provided a straightforward annotation mechanism specifying a set of predefined stereotypes and tagged values. Moreover, it supports already some of the requirements for NFP annotations, such as support for symbolic variables and expressions through its specialized *Tag Value Language* (TVL). However, its approach was not defined formally enough to allow for new user-defined NFP or for different specialized domains. Indeed, SPT defines a grammar for powerful concepts, as for instance “RTtimeValue” expressions, but does not define a mechanism to extend or refine these constructs for more specific needs.

The MARTE NFP modeling framework has reused some useful structural concepts proposed in the UML profile for QoS&FT. However, some considerations to reduce the inherent usage complexity of the UML profile for QoS&FT and to facilitate the modeling process have been taken into account and led to a new proposal. Additionally, as much as possible, features of the SPT profile have been reused. For instance, The Value Specification Language (VSL) introduced in MARTE extends and formalizes (by means of a metamodel and its associated concrete syntax) some concepts supported by TVL to annotate constant, variable, tuple and expression values. In this manner, we provide a flexible and straightforward framework for supporting a wide variety of NFPs annotations while adopting the best modeling practices of both UML profiles.

8.2 Domain View

8.2.1 Overview

The model of a computing system describes its architecture and behavior by means of model elements (e.g.: resources, resources services, behavior features, logical operations, configurations modes, modeling views), and the properties of those model elements. It is convenient to group application properties into two categories: functional properties, which are primarily concerned with the purpose of an application (i.e., what it does at run-time); and non-functional properties (NFPs), which are more concerned with its fitness for purpose (i.e., how well it does it or it has to do it).

In the context of model-driven development approaches for real-time and embedded systems, modeling NFPs is of fundamental relevance and implies a number of design decisions. NFPs provide information about different characteristics, as for example throughput, delays, overheads, scheduling policies, deadline, or memory usage.

In this and subsequent sections, we will use metamodels to describe the domain viewpoint. Note that, although the intent of this domain model is to be precise, it is not fully formal since its purpose is primarily to provide profile’s users with the minimal knowledge to understand the concepts and relationships of the domain.

The NFP annotation framework has many facets that are grouped into individual sub-packages. The overall package structure of the NFP framework is shown in Figure 8.1.

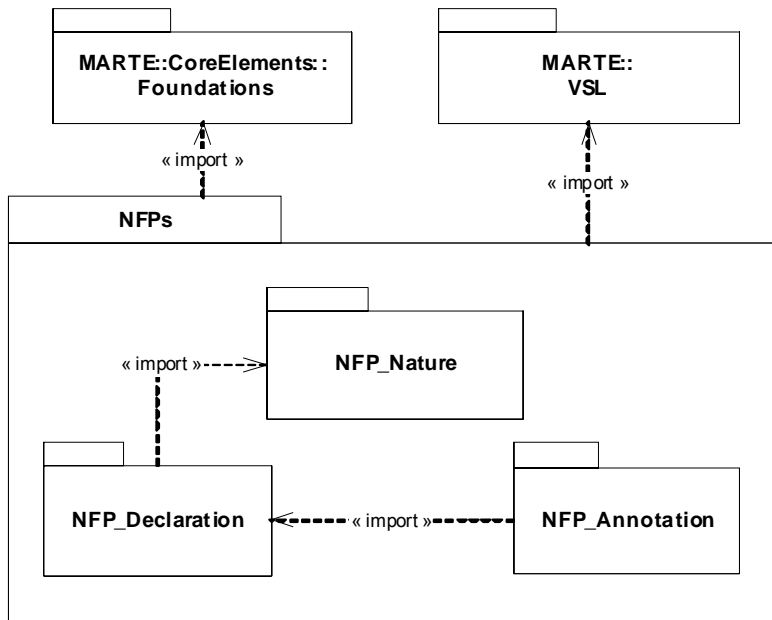

Figure 8.1 - Structure and dependencies of the NFPs modeling package

The purpose and contents of each sub package denoted in the Figure 8.1 are described in subsequent sections.

8.2.2 The NFP_Nature package

From an abstract viewpoint, a NFP (*AbstractNFP*) can be either *qualitative* or *quantitative*, as shown in Figure 8.2.

QuantitativeNFPs are measurable properties. A given quantitative NFP may be characterized by a set of *SampleRealizations* and *Measures*.

SampleRealizations represent a set of values that occur for the QuantitativeNFP under consideration at run-time (for instance, measurements collected from a real system or a simulation experiment). A QuantitativeNFP may be sampled once or repeated multiple times over an extended run. In a cyclic deterministic system, in which each execution cycle has the same value, a single sample is sufficient to characterize completely the QuantitativeNFP.

A *Measure* is a (statistical) function (e.g., mean, max, min) characterizing the set of sample realizations. Measures may be computed either directly by applying the desired function to the set of realizations values, or by using theoretical functions of the probability distribution given for the respective QuantitativeNFP.

According to measurement theory, measures are defined as a *Quantity* expressed in terms of a specific *Unit*. *Quantities* can be basic or derived. *BasicQuantities* are for example length, mass, time, current, temperature or luminous intensity. The units of measure for the basic quantities are organized in systems of measures, such as the universally accepted *Système International (SI)* or International System of Units. Quantities expressed in the same unit can be compared. *DerivedQuantities* (e.g., area, volume, force, frequency) may be obtained from basic quantities by explicit formulas. Additionally, different units of the same physical quantity may be transformed to, or expressed in terms of, existing base units through a given conversion factor and an offset factor.

Figure 8.2 - Domain Model for NFP Nature

QualitativeNFP refer to inherent or distinctive characteristics that may not be measured directly. In general, a qualitative NFP is denoted by a label (e.g., “bronze,” “silver,” and “gold” level of service) representing a high-level of abstraction characterization that is meaningful to the analyst and the analysis tools. More specifically, a qualitative NFP takes a value from a list of allowed values, where each value identifies a possible alternative.

When looking in more detail at a qualitative NFP, it may be possible to define it in function of a set of criteria, which may be in turn qualitative or quantitative. Some qualitative NFPs have known meanings that can be interpreted by particular domains, for example the choice of a scheduler type for a processor, or the choice of a statistical distribution for the latency of a network. In both examples, the full specification of the property requires not only a qualitative value, but also some quantitative parameters, as for instance: scheduler-type = roundRobin (quantumSize) or latency-value = gamma (mean, variance).

8.2.3 The NFP_Annotation Package

Figure 8.3 shows a domain model for NFP annotations. A *model* of a *system* (which is considered in this specification to be expressed in UML) can be extended by *annotated models* with additional semantic expressing concepts from a given *modeling concern* or domain viewpoint. An *annotated model* contains *annotated elements*, which are model elements extended by standard modeling mechanisms. For example, some typical performance analysis-related annotated elements are: *step* (a unit of execution), *scenario* (a sequence of steps), *resource* (an entity that offers one or more services), *service* (offered by a *resource* or by a component of some kind)⁴.

4. The *Step* and *Scenario* model elements are defined in GQAM (Chapter 15), whilst the *Resource* and *Service* model elements are introduced in GRM (Chapter 10)

An annotated element describes certain of its non-functional aspects (i.e., the ones that are directly related to the annotation concern) by means of NFP value annotations. These annotations are specified by the designer in the models and attached to model elements. Thus, the role *nfpValue* on *ValueSpecification* (Figure 8.3) indicates that an annotated model element has a value or values for a specific NFP. *ValueSpecification* is used to define the value expressions associated with NFPs. The values must conform to the defining *NFP* in type and multiplicity. Examples of NFPs are: the total delay of a *step* when executed (including queuing delays), the *utilization* of a resource, and the *response time* and *throughput* of a service.

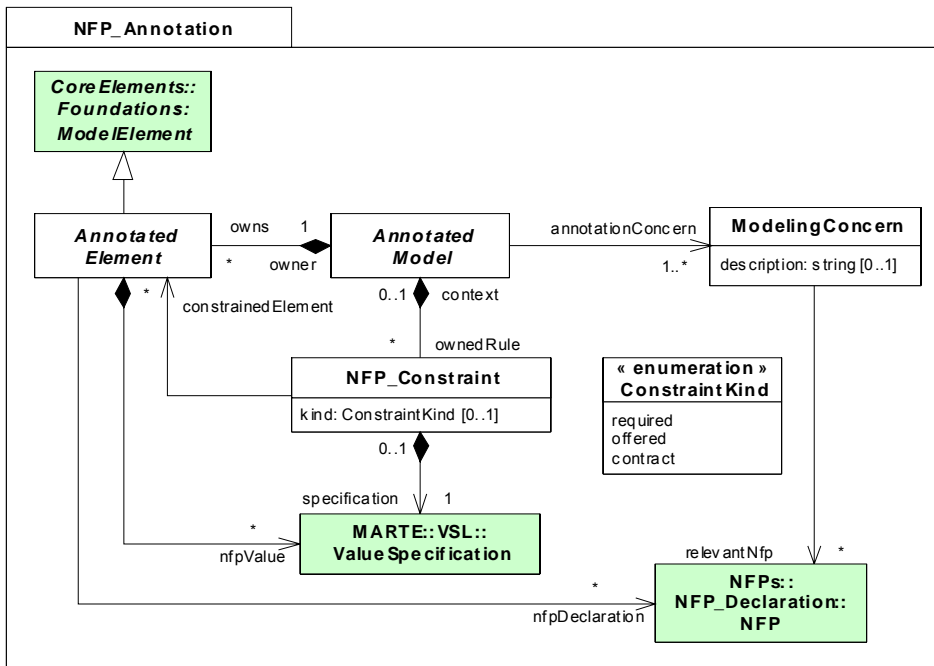

Figure 8.3 - Domain model for NFP annotations

Due to the abstraction involved in the construction of a model, only some NFPs are relevant to a certain *modeling concern*. In other words, a given modeling concern uses a set of NFPs which establishes the ontology of the domain. For instance, specific analysis techniques (e.g., performance or schedulability analysis) deal with distinctive non-functional annotations.

A *NFP_Constraint* is a condition (a Boolean expression) on the non-functional properties associated with model elements. In general, *NFP_Constraints* are assertions that indicate restrictions that must be satisfied by a real-time system. The annotated model defines the context of the constraints for interpreting names used in the value specification. *Kind* of constraints qualifies *NFP_Constraints* by either *required*, *offered*, or *contract* nature. When a constraint is defined as *required*, the values specified in the *NFP_Constraint* indicate the minimum quantitative or qualitative level that the constrained elements demand (these elements are usually clients of resources). An example of required constraints for a *step* element is the maximum latency for execution. *Offered* constraints establish the space of NFP values that can support a model element, as for example the throughput of a CPU (elements in this case are commonly software or hardware resources). *Contract* constraints define conditional expressions that specifies relationships between offered and required non-functional values. For instance, if a given model element (e.g., a computing resource) does not support a condition

on one or many of its NFP values (e.g., a processing capacity), other model element might change one or many of its NFP values accordingly (e.g., the delay to execute a piece of code). In section 8.3.3.2, we give a detailed example of NFP_Constraints usage.

8.2.4 The NFP_Declaration package

NFP declaration is intended to qualify and assign extended data types to NFP values (Figure 8.4).

On the other hand, NFP elements have a *TupleType* (see Annex D for MARTE extended data types), called *NFP_Type*. Two attributes define the body of NFP types: *valueAttribute* and *exprAttribute*. *ExprAttribute* is used to specify expressions associated with NFPs. Hence, we are able to assign variables, literals, intervals, and other expressions. The return value of the expression must be conform to the associated *value* attribute of NFP type.

NFP_Type adds the ability to carry a measurement *unit* (by means of *unitAttribute*) and additional qualifiers to NFP values (*qualifierAttributes*).

A *NFP_Type* with measurement unit is associated with physical measures. Units are attributes of most *Quantitative NFP* elements and it is important to use standard forms. In Section 8.3.3.1, we show some pre-declared units largely used in the domain (e.g., time units, data size units, transmission speed units) which can be used when specifying NFP values.

Examples of qualifiers are *statisticalQualifier*, *direction*, *value source*, *measurement precision* and (see NFP Types Library in Section 8.3.3.1). A *statisticalQualifier* indicates the type of statistical measure of a given property (e.g., maximum, minimum, mean, percentile, distribution). The *direction* attribute (i.e., increasing or decreasing) defines the type of the quality order relation in the allowed value domain of NFPs. Indeed, this allows multiple instances of NFP values to be compared with the relation "higher-quality-than" in order to identify what value represents the higher quality or importance. *Source* is a peculiarity of non-functional properties associated with the origin of specifications. *Precision* is the degree of refinement in the instruments and methods used to obtain a result.

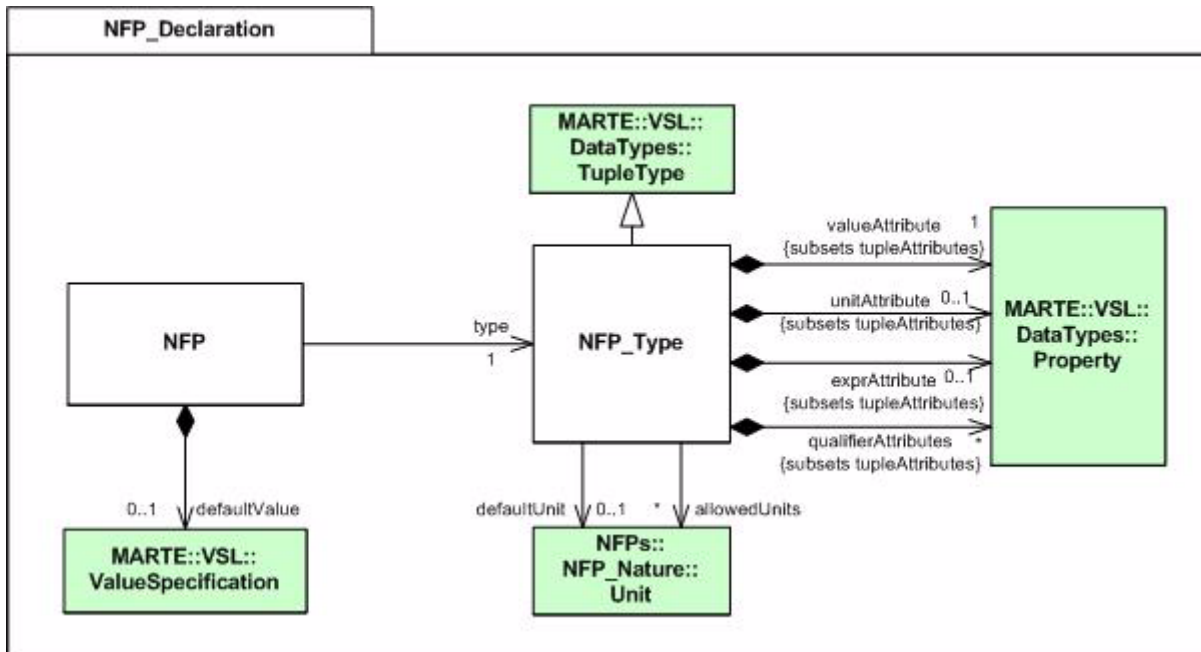

Figure 8.4 - Domain Model of NFP Declaration

Notice that the set of concepts supporting the declaration of NFPs provides means to annotate NFPs in a first phase, but the concrete infrastructure for specifying values is supported by VSL (Annex B). Nevertheless, default measurement units and values may be assigned when declaring NFPs and NFP types.

The ability to specify all the kinds of values supported by VSL is a key concern for NFP annotations. Indeed, NFP specifications needs to be composable. That means, it should be possible to specify NFP values at a fine-grained level and compose them into higher-level specifications. Conversely, a high-level NFP specification should be decomposable such that fine-grained NFP specifications can be refined. The refinement relationship between two levels of NFP specification must ensure consistency between both levels. The process of composition and decomposition should be carried out in such a manner as to guarantee this consistency. NFP specifications should be able to be refined so that new NFP specifications can be based on existing ones.

8.3 UML Representation

This section describes the UML extensions required to support the concepts defined in the previous domain view. The set of extensions to support NFP modeling with UML is organized according to the application context of the domain concepts. In particular, in the NFP modeling framework, note that not every domain concept will result directly in a UML stereotype or tagged value. This is because some domain concepts are abstract, representing generalizations that will not appear directly in any UML model.

For instance, the abstract notion of a “Measure” is very useful as an abstraction in our framework, but will only be manifested in its concrete forms (e.g., delay, throughput, capacity) in MARTE models. While a corresponding stereotype could have been defined for this abstract concept, it would never be used in practice. Therefore, we have chosen to only define stereotypes for concepts that we envisage are actually going to be used in practical modeling situations. This results in a simpler and more compact profile.

Thus, we first describe the extensions concretized in stereotypes. In Annex D, a set of NFP Types is predefined, which is used extensively in MARTE to type and qualify non-functional properties.

In Section 8.3.3.2, we will describe some examples that use the whole extensions for NFP annotations with both tagged values and UML constraints.

8.3.1 Profile diagrams

The Figure 8.5 shows the UML extensions for NFP modeling. The *NFP Modeling* package (stereotyped as *profile*) defines how the elements of the domain model extend metaclasses of the UML metamodel. These stereotypes are listed in alphabetical order. The semantic descriptions corresponding to these stereotypes and their properties are provided in the following section.

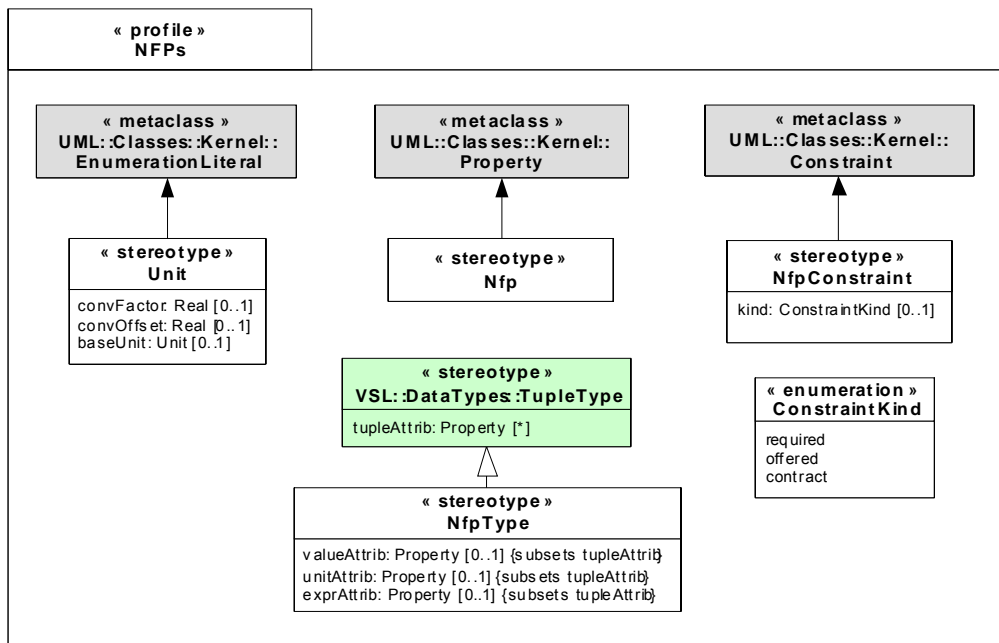

Figure 8.5 - UML profile diagram for NFPs modeling

8.3.2 Profile elements description

8.3.2.1 Nfp

The *Nfp* stereotype maps the NFP domain element (Section F.2.10) denoted in Annex F.

Non-Functional Properties (NFPs) declares an attribute of one or more instances in terms of a named relationship to a value or values. *Nfp* is intended to declare, qualify and assign extended data types to NFP values.

Extensions

- Property (from UML::StructuredClasses::Kernel)

Generalizations

- None

Associations

- None

Attributes

- None

Constraints

- None

8.3.2.2 NfpType

This *NfpType* stereotype maps the *NFP_Type* domain element (Section F.2.12) denoted in Annex F. Note, however, that the *qualifierAttributes* role is not implemented in the UML view. In practical terms, the *tupleAttribute* inherited from *TupleType* is sufficient to define qualifier attributes.

A Nfp type is a type whose instances are identified only by NFP value specifications. A Nfp Type contains specific attributes to support the modeling of NFP tuple types.

Extensions

- DataType (from UML::StructuredClasses::Kernel)

Generalizations

- TupleType (from VSL::DataTypes) on Annex B.3.2.5.

Associations

- None

Attributes

- valueAttrib: Property [1]
both physical and non-physical NFP types have a *value* attribute, which serves as placeholder to specify a value of NFPs.
- unitAttrib: Property [0..1]
measurement unit declaration that apply to all the value specifications of the NFP. Usually, it is an enumeration data type with a list of the valid measurement units.
- exprAttrib: Property [0..1]
attributes representing an expression. MARTE uses the VSL language to define expressions.

Constraints

- None

8.3.2.3 NfpConstraint

This *NfpConstraint* stereotype maps the *NFP_Constraint* domain concept (Section F.2.11) denoted in Annex F.

NfpConstraint extends the UML mechanism for applying a condition or restriction to modelled elements. Specifically, NFP constraints support textual expressions to specify assertions regarding performance, scheduling, and other embedded systems' features, and their relationship to other features by means of variables, mathematical, logical, and time expressions.

Extensions

- Constraint (from UML::StructuredClasses::Kernel)

Generalizations

- None

Associations

- None

Attributes

- kind: ConstraintKind [0..1]
tagged definition qualifying NFP constraints by either required, offered, or contract nature.

Attributes

- None

Constraints

- None

8.3.2.4 Unit

This *Unit* stereotype maps the *Unit* domain element (Section F.2.18) denoted in Annex F.

Unit is a qualifier of measured values in terms of which the magnitudes of other quantities that have the same physical dimension can be stated. A unit often relies on precise and reproducible ways to measure the unit. For example, a unit of length such as meter may be specified as a multiple of a particular wavelength of light. A unit may also specify less stable or precise ways to express some value, such as a cost expressed in some currency, or a severity rating measured by a numerical scale.

Unit is defined as a stereotype of EnumerationLiteral. This allows modelers to assign a list of allowed units to a particular physical NFP type by means of a related Enumeration element. In this way, we bound the universe of legal units that apply to a specific kind of NFPs.

Units can be declared with a parameter representing the *Conversion Factor* that is applied to a *Base Unit* to determine the value in terms of the specified measurement unit.

Extensions

- EnumerationLiteral (StructuredClasses::Kernel)

Generalizations

- None

Associations

- None

Attributes

- convFactor: Real [0..1]
This parameter allows referencing measurement units to other base units by a numerical factor.
- offsetFactor: Real [0..1]
This parameter allows referencing measurement units to other base units by applying an offset value to them.
- baseUnit: Unit [0..1]
This attribute represent the base unit by which a derived measurement unit is created
Basic units do not require this attribute.

Constraints

- None

8.3.3 Graphical Syntax of NFP Value Specification

In this section, we define an alternative graphical syntax for value specifications having NfpType as data type. This syntax consists of a pair of a value and a unit:

```
<nfp-value> ::= <value-specification> [ ' ' <unit-enumeration> ]
```

The following are typical examples:

5 ms # a duration value

50 kHz # a frequency value

Note that this notation is for the graphical view of models only. The tuple notation (see Section B.3.3.9) is still valid for NFP values (NfpType inherits from VSL::TupleType), both in graphical models and in the repository as well. For instance, the NFP value: '50 kHz' can be specified in the model repository as: '(50, -, kHz, max, -, est, -)' or '(value=50, expr=null, unit=kHz, statQ=max, dir=null, source=est, precision=null)'.

The main rationale of the "value-unit" notation is readability of graphical models. Specific tools could provide more flexibility in the graphical notation. For instance, users may be able to customize the elements of a tuple in a NFP value specification that should be displayed. However, because of its common usage in engineering models in general, the "value-unit" notation is normative (although not mandatory) in MARTE.

8.3.4 Examples

A requirement for NFP annotations is a trade-off between usability and flexibility. Usability suggests the merit of declaring a set of standard NFPs for a given modeling domain, so they can be easily referred to and, consequently, every user of the annotations means the same thing. For NFPs with well-known variants, a set of declarations can be standardized, which cover the important cases with differently-named measures; these can be translated if necessary by domain specialists for the use of a specific tool with different names. However there are some NFPs whose meaning is domain- or even project-dependent. This requires a capability for users to define their own NFPs. Thus flexibility and expressive power requires that the users have the capability to define their own NFPs, but usability requires a set of standard measures that can be used in straightforward way.

The following sections will describe respectively an example of NFP model library and examples of usage of such library.

8.3.4.1 Example of NFP model library definition

This section provides an example of NFP types model library definitions. This example corresponds to an excerpt of a more complete model library predefined for MARTE and specified in detail in Annex D.1. This MARTE library includes predefined data types supporting NFP annotations commonly used in the real-time and embedded system domain.

NFP Types are implemented in MARTE through UML data types. UML data types (DataType metaclass) are special kind of classifiers, similar to classes. A data type differs from a class in that instances of a data type are identified only by their values. Like a class, data type may have attributes. In VSL, we define four kinds of composite data types (data types allowing attributes): IntervalType, CollectionType, ChoiceType and TupleType. data types with attributes of different types are called *TupleTypes* (see Annex D in p.395 for MARTE extended data types). If a tuple type has attributes with different types, then instances of that data type will contain attribute values matching the types of their corresponding attributes. Particularly in MARTE, we define a set of pre-declared NFP types which are useful for the other sub-profiles. However, other domain-specific libraries can be defined either using the NFP profile or specializing the MARTE libraries.

Figure 8.6 shows the package pre-declaring NFP types. Note that we import the MARTE primitive types defined in the VSL annex (Annex B, p. 353). The list of MARTE primitive types includes *Real and DateTime* in addition to the pre-declared UML primitive types. However, note that the set of UML primitive types are completely redefined within MARTE in order to allow specifying operators on these types (more rationales on this are provided in annex D.1).

General MARTE data types that are not NFP types are declared in the *MARTE_DataTypes* library (Annex D). This library uses stereotypes of the VSL Profile for data types (see Annex B).

General MARTE NFP types are declared in the *BasicNFP_Types* library (Annex D). A root NFP type called *NFP_CommonType* is defined to factorize common NFP type attributes.

In addition to value, expression and unit attributes, NFP types are declared specifying a set of qualifier attributes required to precisely specify and qualify NFP values.

The semantic of the provided qualifier attributes is the following:

- source: SourceKind [0..1]
peculiarity of NFPs associated with the origin of specifications. Predefined kind of sources for values are *estimated, calculated, required* and *measured*.
- precision: Real [0..1]
degree of refinement in the performance of a measurement operation, or the degree of perfection in the instruments and methods used to obtain a result. Precision is characterized in terms of a Real value, which is the standard deviation of the measurement.
- statQ: StatisticaQualifierKind [0..1]
statistical qualifier indicates the type of “statistical” measure of a given property (e.g., maximum, minimum,

mean, percentile, distribution).

- dir: DirectionKind [0..1]
direction attribute (i.e., increasing or decreasing) defines the type of the quality order relation in the allowed value domain of NFPs. Indeed, this allows multiple instances of NFP values to be compared with the relation “higher-quality-than” in order to identify what value represents the higher quality or importance.

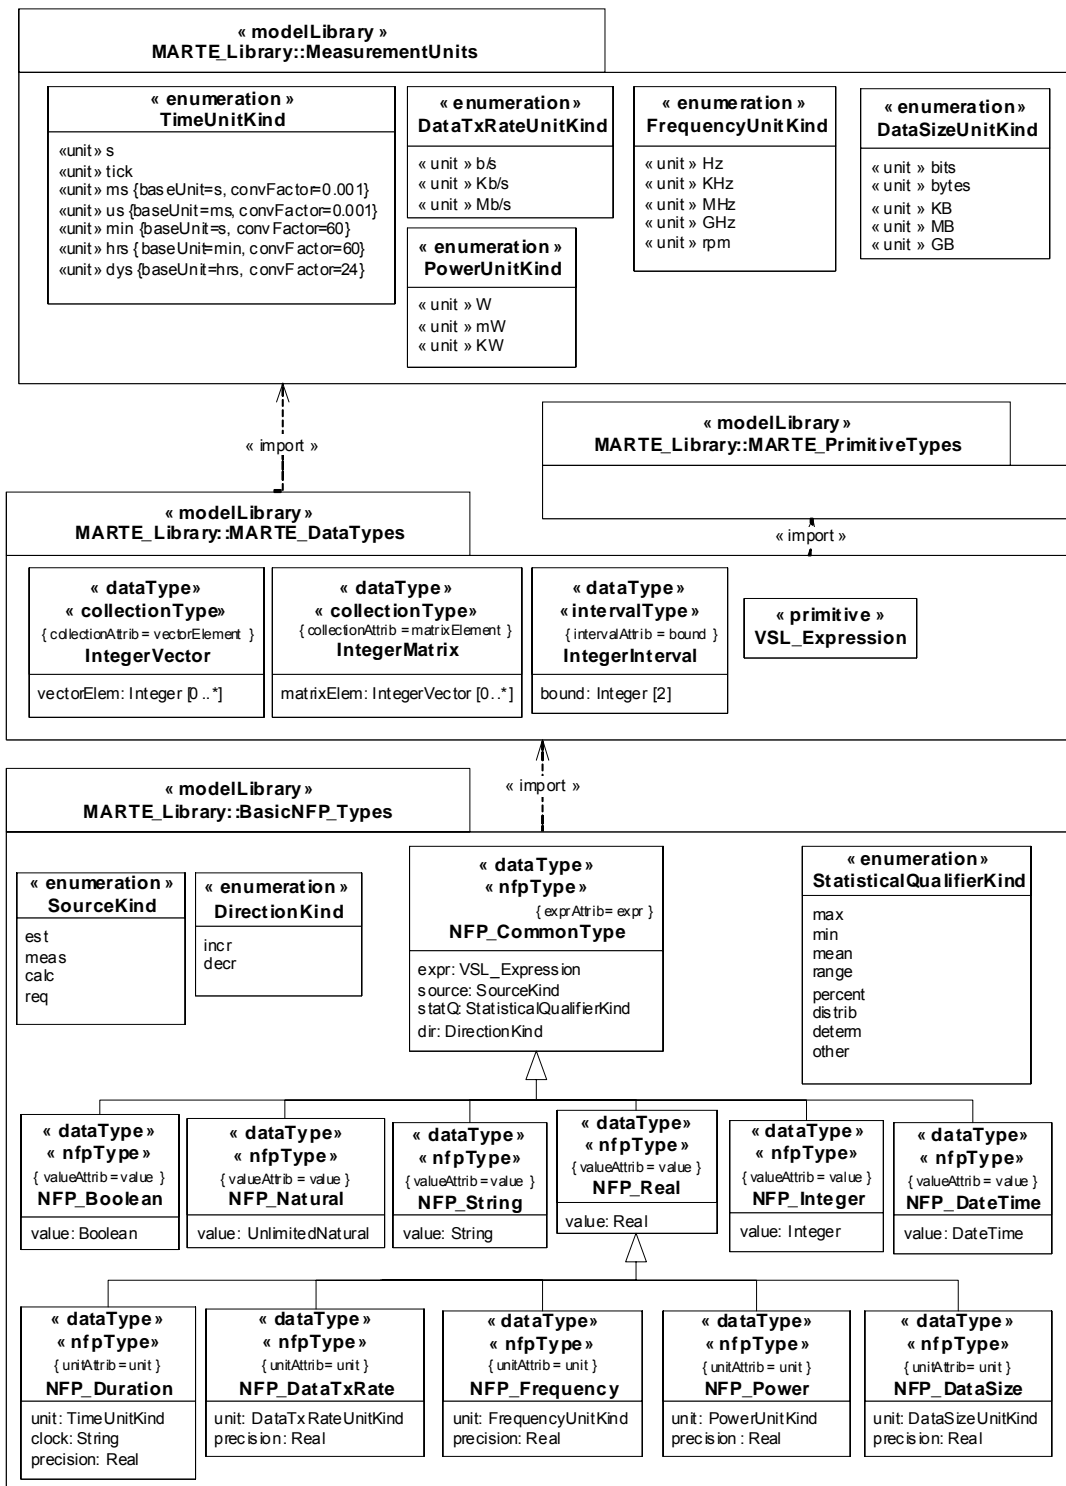

Figure 8.6 - Extract of the model library defining the pre-declared Basic NFP Types and measure units

Additionally, although not shown in Figure 8.6, we include a set of probability distribution operations that can apply to the pre-declared NFP Types. *Probability distribution* is a fundamental concept to specify stochastic values. A probability distribution assigns to every interval of the real numbers a probability, so that the probability axioms are satisfied. In technical terms, a probability distribution is a probability measure whose domain is the Borel algebra on the reals. A probability distribution is modeled in MARTE as the name of the function and a set of parameters allowing estimating the function in terms of the standard form of the distribution.

Probability distributions are defined as *operations* of NFP types, each with particular parameters. The included probability distribution function values are described by the following:

- bernoulli (prob: Real)
Bernoulli distribution has one parameter, a probability (a real value no greater than 1):
- binomial (prob: Real, trials: Integer)
binomial distribution has two parameters: a probability and the number of trials (a positive integer):
- exp (mean: Real)
exponential distribution has one parameter, the mean value:
- gamma (k: Integer, mean: Real)
gamma distribution has two parameters (“k” a positive integer and the “mean”):
- normal (mean: Real, standDev: Real)
normal (Gauss) distribution has a mean value and a standard deviation value (greater than 0).
- poisson (mean: Real)
Poisson distribution has a mean value:
- uniform (min: Real, max: Real)
uniform distribution has two parameters designating the start and end of the sampling interval:

Two kinds of data types are defined: physical dimension types and dimensionless types. In this latter group, we define all the data types supporting NFP literal values (e.g., *NFP_Real*, *NFP_DateTime*, *NFP_Boolean*). For dimensionless types, the value attribute is typed according to the related primitive type. For dimension types, the value attribute has the primitive type Real. This has a practical definition intended to allow modelers representing measured NFP values in the domain of real numbers. Note that this set of dimension types is not a complete one, since in Annex D, we include additional time and non-time specific NFP types as predeclared MARTE data types.

The time at which a VSL expression is evaluated depends on different factors. For example, some expressions could be evaluated when a resource allocation at modelling level is done. Other properties may be evaluated when a given “real time situation” is modelled. Analysis tools could also provide evaluation of certain expressions.

Notice that dimension types have measurement units. The *BasicMeasurementUnits* package (stereotyped «*modelLibrary*») define a set of measurement units which are useful for the MARTE scope. We apply to this package the «*unit*» stereotype defined in the NFP profile. As illustrative examples, we show in Figure 8.6 some units used in the MARTE domain (a complete MARTE library for measurement Units is shown in Annex D.1). It holds a set of self-defined units, as for example: “s” denoting the time unit for “seconds”. Other derived units are defined with basis on basic units. For instance, “ms” denotes a time unit obtained with basis on “seconds” by a conversion factor of “0.001”. Modelers are able to define further units in the same way.

8.3.4.2 Usage example of NFP model libraries

We consider three annotation mechanisms: *Tagged Values*, *Constraints*, and (*Instance Specification*) *Slots*. Tagged values are a kind of value slots associated with attributes of specific UML stereotypes. Hence, one tagged value characterizes just one model element. On the other hand, a constraint is a condition expressed in natural language text or in a machine-readable language (e.g., OCL) for declaring some semantics of one or various model elements. This is useful if we define NFPs that involve more than one element (for instance, a delay between two different events). On the other hand, NFP annotations in instance specification slots are related to classifier-defined NFPs. Thus, while the stereotype attribute mechanism implies the creation of UML profiles, the two latter are mainly aimed at supporting user-defined NFPs.

We explore the capabilities of the NFP modeling framework to annotate NFPs by means of stereotypes and tagged values. In Figure 8.7, we show a generic scheme to define and apply NFPs. The *Basic_NFP_Types* package (stereotyped *modelLibrary*) corresponds to that presented in Figure 8.6. It encloses the general NFP types and their default measurement units supporting NFP annotations through all the UML profile for MARTE. Additionally, we depict an extract of the UML sub-profile for GQAM (*Generic Quantitative Analysis Modeling*) (detailed in Chapter 15), which uses the basic NFP Types. To illustrate annotation examples we present a small example of modeling for quantitative analysis.

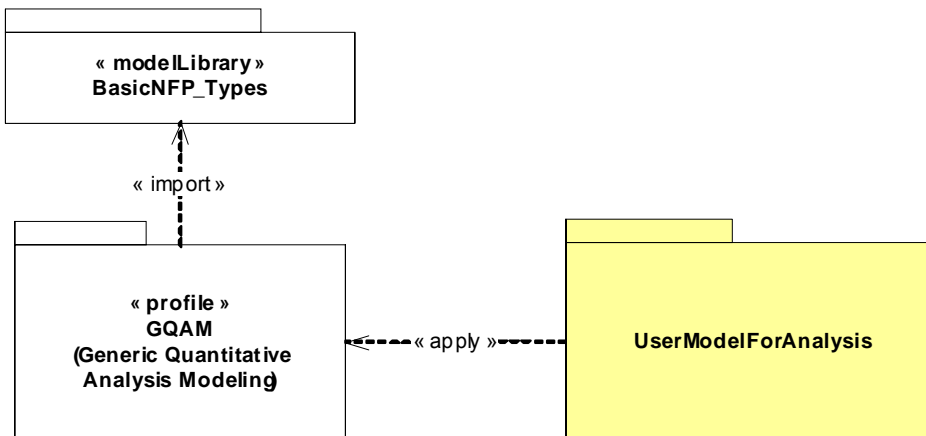

Figure 8.7 - General Structure for Declaring and Annotating NFPs

In the GQAM “profile” package (Figure 8.8), we illustrate a description of one of the stereotypes defined in chapter 15 and some of its property definitions. The example’s intent is to show some particulars of the extension mechanisms used in the NFP modeling framework. These arise from the fact that we use NFP annotations for defining most of types of the stereotype attributes. This feature provides more flexibility to the profile and full compliance with the profile extension mechanism provided by UML2. The *«gaExecHost»* stereotype, which represents an execution resource with annotations for analysis, has *efficiency* properties (e.g., *utilization*), and *overhead* properties as for example *cntxtSwT* (*context switch time*), *clockOvh* (*clock overhead*). These attributes are then typed with the NFP Types defined in the *Basic_NFP_Types* model library (e.g., *NFP_Duration*, *NFP_Real*), which, in turn, contains the tuple information of NFPs. At this stage, we use the NFP qualifiers *statQ* (statistical qualifier), *dir* (direction) and *unit* (measurement unit) as default values of NFPs to define the exact semantic of the non-functional attributes. However, this does not prevent modifying these attributes for specific instances.

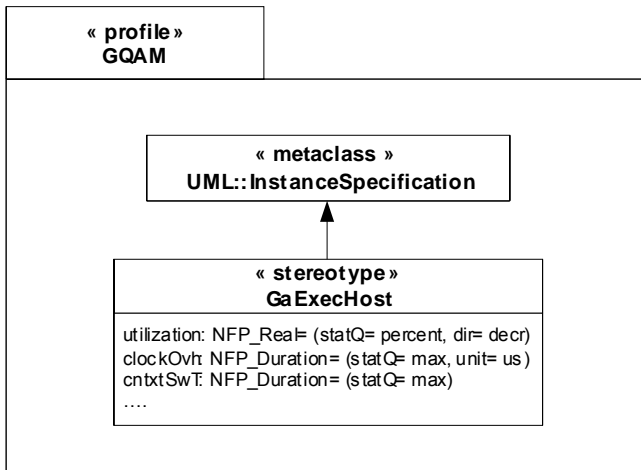

Figure 8.8 - An example of declaration of NFPs in stereotype attributes

The use of this profile definition is shown in the package named *UserModelForAnalysis* (Figure 8.9). In this model, an instance of a *node* model element is stereotyped «*gaExecHost*». The associated tagged values of this stereotype are shown in a compartment (see notation alternatives in the UML Superstructure document, Chapter of Profiles). We can see that tagged values are specified as structured data types. For example, *clockOvh* is a tuple value that has expression and source item values. The expression: “normal(50,7)” is a *CallOperationExpression* (see the VSL annex, package Expressions, for further details) which calls the probability distribution operation of the defining NFP type (*NFP_Duration*). The *utilization* tagged value is specified as an expression string making reference to a variable *\$u1*. As a methodological rule that we adopted in the analysis sections, variables indicate to analysis tools that these attributes must be computed and returned to the UML model. Note that the default values defined in the stereotype attribute declarations can be overridden in the tagged values if required. For instance, the measurement unit of *clockOvh* has been overridden in our example.

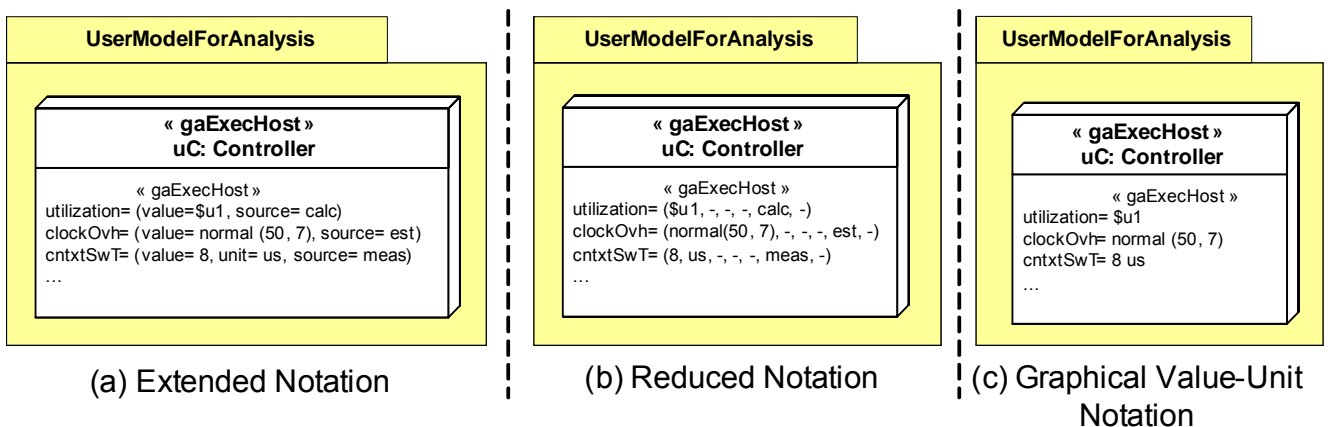

Figure 8.9 - Example of user model for analysis with NFP annotations

The second mechanism considered to annotate UML models with non-functional aspects is through *NFP Constraints*. Constraints commonly define relational expressions between two terms containing parameters, specified by means of VSL variables or UML properties, and possibly numeric values. Such constraints can be used to identify critical performance parameters and their relationships to other parameters on the system modeled.

The third NFP annotation mechanism is by using slots of UML Instance Specifications. For this purpose, NFPs are to be declared at classifier level and NFP values are specified within the related slots. This mechanism has the disadvantage that annotations are confined to classifiers' instances.

Figure 8.10 shows an example for using the two latter annotation mechanisms (constraints and slots). An important aspect to have in mind regarding this particular example is that we *declare* NFPs at user model level, instead of defining NFPs as stereotype attributes like in the formerly illustrated mechanism. Our aim is to show how modelers can define their own NFPs and use them to specify NFP values by means of *NfpConstraints* and *Slots*. Hence, in such cases, the semantics of the defined NFPs is user-dependent⁵.

5. Note that, in general, if modelers will use the different MARTE sub-profiles, they should follow the annotation mechanism of stereotype attributes and tagged values to specify NFPs and NFP values. The approach illustrated in the second example has been included in MARTE in order to support user model-defined (or library-defined) NFPs.

Figure 8.10 - Example of user model with NfpConstraint and Slot annotations

We defined a classifier, named *Controller*, that owns a set of properties stereotyped as `«nfp»`. Note that we have declared similar NFPs as in the previous example, but we intentionally changed their names to emphasize the fact that, in this case, the declared NFPs have user-specific meaning. As for the stereotype annotation mechanism, in this example we use *NFP_Types* to define the structure of NFP value specifications. We also defined default values for NFPs, which state the predefined value qualifiers: statistical qualifier, direction and unit.

We created a *uC* instance of *Controller* and then specified its internal structure by means of a Composite Structure diagram. These instance-level model elements are stereotyped with high-level modeling constructs, `«computingResource»`, `«scheduler»`, and `«clockResource»`, which are formally introduced in the GRM sub-profile, Section 10.3. At this stage, we specify a set of NFP values by means of two *NfpConstraints* attached to the specific constrained elements. In both cases, the *constrainedElement* (association end from the UML Constraint metaclass to UML Element metaclass) are the specific

model elements to which the non-functional annotations apply, and the context (association end from the UML Constraint metaclass to the UML Namespace metaclass) is the Controller node element, which actuates as a namespace context for VSL expressions.

For instance, one of the *NFP_Constraints* is attached to the *sysScheduler part* element. This one defines an “offered” non-functional constraint written in VSL (see Annex B for details on the VSL textual language). The VSL expression is a three-level nested boolean expression. In the first level, an infix *CallOperationExpression* makes reference to the “and” operation (see the list of operations in Annex D) by specifying two operands. These operands are in turn other *CallOperationExpressions* making reference to the *equalTo* (“==”) operation, which has two operands. The first operand in both cases is *PropertyCallExpression* (calling to the *contextSwitch* and *schedUtiliz* properties of Controller) and the second operand in both expressions is a particular value that is conform to the defining property. In simple words, VSL allows for specifying NFP values by using (NFP) properties previously declared in the model.

In order to complement this basic annotation, a more complex *NFP_Constraint* has been specified for the *procClock* par (processor clock instance). We illustrate a non-functional *contract* assertion that is intended to be allowed at run time. When the Controller *utilization* becomes greater than 90%, the clock’s frequency increase from 20 MHz to 60 MHz. In this example, we do not make any assumption about the run-time mechanisms supporting this assertion. The contract has been specified by using a *VSL Conditional Expression*, whose structure is detailed in Figure 8.10.

The third proposed annotation mechanism is depicted by defining a *procUtiliz* slot within the *uC* instance of *Controller*. As in the first example (Figure 8.9), the *utilization* slot is specified by a variable *\$u1*. The methodological rule indicates, again, that this variable should be computed by analysis tools and returned to the UML model.

Additional examples of VSL time expressions and the constraint annotation mechanism are given in Annex B.

9 Time Modeling (Time)

This chapter contains both domain and UML viewpoints for time modeling. The chapter describes a general framework for representing time and time-related concepts and mechanisms that are appropriate for modeling real-time and embedded systems. These serve as a base for the standard modeling elements defined in subsequent chapters of the MARTE profile.

Since Real-time systems are specifically concerned with the cardinality of time (e.g., delay, duration, clock time), (chrono-) metric time will be considered. Embedded systems may also require logical time models. Thus, both logical and metric times are covered in this specification.

9.1 Overview

The time domain model described in this chapter identifies the set of time-related concepts and semantics that are supported by this profile. The model is quite general, and a given application may need to use only a subset of its proposed concepts and semantics.

Time can be differently perceived at the different phases of the development of an embedded real-time system (modeling, design, performance analysis, schedulability analysis, implementation, etc). The concept of ordering (i.e., something occurring before or after another thing) is common to many Time representations. MARTE adopts models of time that rely on partial ordering of instants. The temporal ordering of behavior activities can be represented in many ways, depending on the level of precision required. There are three main classes of time abstraction used to represent behavioral flows (with minor variations at each level). They are known under different names in different contexts, and these names are also often used with different meanings elsewhere (so there is no general consensus):

- **Causal/temporal:** in such models, one is only concerned about instruction precedence/dependency. These relations can be partial in presence of concurrency. Cooperation between concurrent entities takes place as communications (i.e., through events). Communications themselves can be fully asynchronous, blocking (with the emitter awaiting a returned reply), or hand-shake synchronization.
- **Clocked/synchronous:** this class of time abstraction adds a notion of simultaneity, and divides the time scale in a discrete succession of instants. Rich causal dependencies can take place *inside* an instant, leading to the “*instantaneous reaction*” abstraction. When the clock(s) is (are) linked to a regular pulse, clock ticks become the unit scale of a discrete-time model (but this need not be the case in any “synchronous” temporal model). This level is used in hardware modeling (at RTL level) where instantaneous propagation corresponds to “combinatorial” behaviors, in simulation formalisms (as in MATLAB® / SIMULINK®, or in Hardware Description Languages such as SystemC/VHDL/Verilog with δ -cycles representing causal zero-delay dependencies), or in software modeling when relying on synchronous languages semantics (such as Esterel or SCADE or Signal). A generalization of the synchronous domain allows clocked entities to be linked in a looser, asynchronous network where no single-clock domain is defined. It leads to the notion of GALS (Globally-Asynchronous/Locally-Synchronous) domains. These are used in the field of system-level models, for instance for SoC (System-on-Chip) design, where several levels of modeling – either software or hardware – can be combined during the course of the design.
- **Physical/real-time:** this class of time abstraction demands the precise accurate modeling of real-time duration values, for scheduling issues in critical systems. Physical time models can also be applied to clocked model, for instance to derive the admissible speed of a reaction.

In embedded real-time systems modeling, time should not be considered as an external model: Time and Behavior are strongly coupled. The Time domain model identifies concepts that relate time and behavior. The Causality package in the CoreElements chapter of MARTE has provided a high-level view of the run-time semantics of real time and embedded

systems. The Time modeling chapter enriches this view with *explicit references to time-related concepts*. The Invocation package in the CoreElements chapter is also extended with the concept of *SimultaneousOccurrenceSet*. The notion of *instant* has also to be revisited to deal with *simultaneity*. This is done in the *TimeStructure*⁶, which represents Time as a partial ordering of instants. A timed event occurrence refers to one instant. An object may be bound to a time structure by a time base. A time base is a set of instants at which the executions hosted by the object may take place. Time may be the physical time, with its presumed regularity, but it can also be some endogenous time linked to some repetitive event, not directly bound to physical time. Hence, the idea to associate time structure with events, behaviors, and objects, or more generally instances of the concrete subtypes of the *BehavioeredClassifier* metaclass.

To capture the influence of Time on behaviors, we propose that objects, behavior executions, and event occurrences may explicitly refer to *clocks* considered as accessors to the *time structure*.

9.2 Domain view

This chapter covers different concerns about time modeling and usage, informally shown in Figure 9.1. This figure is not a UML diagram. It only gives an overview of the concepts covered by the Time Modeling chapter and their logical grouping.

Figure 9.1 - Overview of the time model concerns

These concerns are reflected in the structure of the time domain model which is partitioned into the following separate but related groups of concepts:

- Concepts for modeling a simple form of time structured as a totally ordered set of instants owned by a time base (*TimeStructure* concern as depicted in Figure 9.1).
- Concepts for modeling multiple time base models (*TimeStructure* concerns as depicted in Figure 9.1).
- Concepts for accessing to time structure, including clocks and time values (*TimeAccess* and *TimeValueSpecification* concerns as depicted in Figure 9.1).
- Concepts for modeling entities bound to time (*TimeUsage* concerns as depicted in Figure 9.1).

6. *TimeStructure* is refined into both *BasicTimeModels* and *MultipleTimeModels* packages in the rest of the chapter.

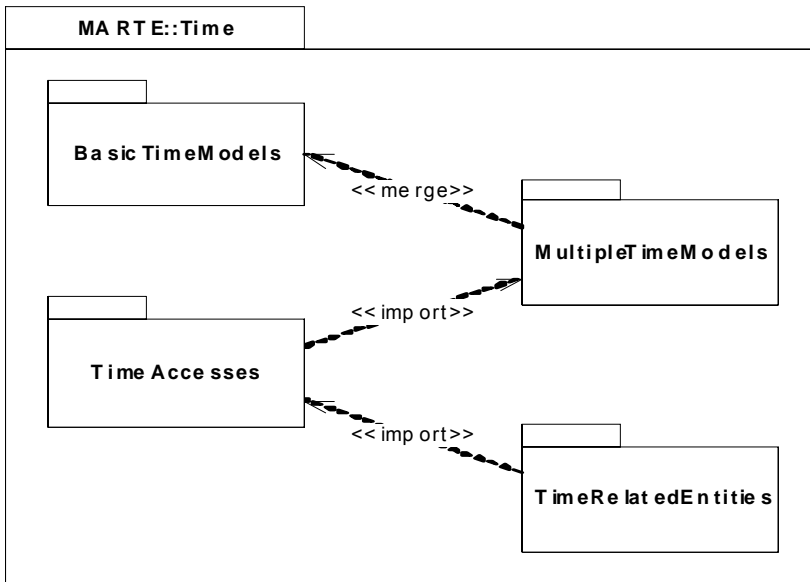

Figure 9.2 - Structure of the Time domain model

The *BasicTimeModels* and *MultipleTimeModels* packages provide a structural model of time (the *TimeStructure*) that constitutes the semantic foundation of our approach to time. These two packages are merged because the concept of *TimeBase* introduced in the former is enriched in the latter. Both packages are used by the *TimeAccesses* and *TimeRelatedEntities* packages that contain concepts and constructs effectively used by the standard user of the profile.

9.2.1 The BasicTimeModels package

The *BasicTimeModels* package (Figure 9.3) provides a structural view of time as an ordered set of instants. This model does not refer to any notion of physical time. Hence, it can conveniently support *logical time*, which is widely used in distributed systems and synchronous languages. This model of time focuses on the ordering of instants, while ignoring the physical duration between successive instants.

A *TimeBase* is a container of *Instants*. The structure of time is specified by the *nature* attribute that takes its values in the enumeration *TimeNatureKind*. Possible values are *discrete* or *dense*. In dense time, for any given pair of instants there always exists at least one instant between the two. A *TimeBase* owns an ordered set of *Instants*. We consider only countable sets. For a discrete time base, instants can be indexed by positive integers. For a dense time base, instants can be indexed by rational number. Notice that continuous time models, whose indices would be real numbers, can not be fully represented by countable sets. Since UML behavioral semantics only deal with discrete behaviors, the countable nature of sets is not a limitation for practical uses.

In order to avoid duplication of concepts based on a distinction between dense and discrete representations, all the numbers are given using a unique predefined data type *Real*, which expresses the mathematical concept of a number, covering integer, rational and real numbers. A real represents a count or a measurement. The primitive type *Real* does not impose any restrictions on the precision and the scale of the representation.

Since discrete time bases play a central role in the time structure model, it is convenient to distinguish a special class for discrete time bases, which subclasses *TimeBase*. Junction instants are specialized instants (their name will be justified in the *MultipleTimeModels* package). A discrete time base owns junction instants only. This does not preclude a dense time base from owning junction instants.

The association between a discrete time base and a time base optionally enables to link a discrete time base to a dense time base. In this case, the former results from a discretization of the latter.

Figure 9.3 - Basic time diagram of the time model

Physical time is considered as a continuous and unbounded progression of physical instants. Physical time is assumed to progress monotonically (with respect to any particular observer) and only in the forward direction. For a given observer, it can be modeled as a dense time base. A convenient model for Physical Time as perceived in MARTE is the mathematical concept of real line R .

9.2.2 The MultipleTimeModels package

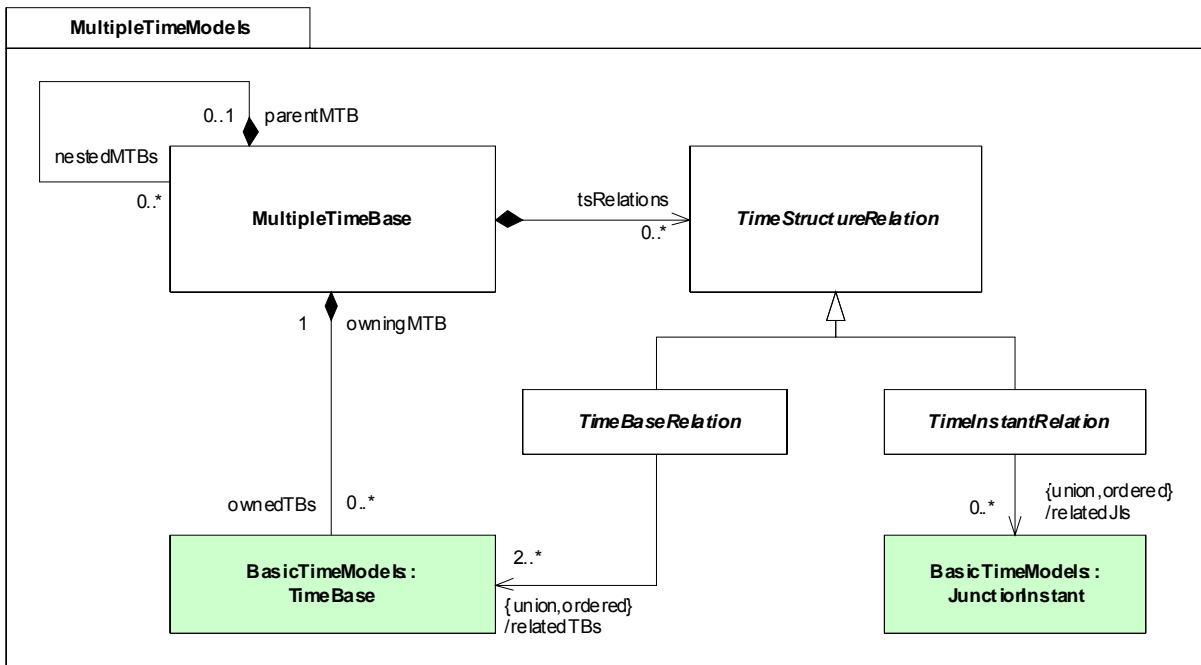

Figure 9.4 - Multiple time diagram of the time model

The linear vision of time presented in the *BasicTimeModels* is not sufficient for most of the applications, especially in the case of distributed systems. Multiple time bases are then used. A time structure contains a tree of multiple time bases. A *MultipleTimeBase* consists of one or many time bases. A time base is owned by one and only one multiple time base.

Time bases are a priori independent. They become dependent when instants from different time bases are linked by relations (Time Instant Relations). Note that the word *relation* has been preferred to *relationship* in order to stress on the mathematical meaning of this word. The instants involved in such relations are special instants called *junction instants*, previously introduced in the *BasicTimeModels* package (Figure 9.3). All the instants of a discrete time base are also junction instants, because they are potentially observable instants (see the subsection 9.2.3 about Time Access, page 74).

A multiple time base owns a possibly empty set of time structure relations. These relations specify the time structure. *TimeStructureRelation* is an abstract class. It is subclassed into *TimeBaseRelation* and *TimeInstantRelation*, which are also abstract classes. A time base relation relates 2 or more time bases. A time instant relation relates 0 or more junction instants. Notice that the *relatedTBs* and *relatedJIs* properties are derived union (i.e., the effectively related elements are defined in concrete subclasses, as illustrated in the next 2 sections).

9.2.2.1 Concrete time instant relations

Figure 9.5 - TimeInstantRelation diagram of the time model

As shown in Figure 9.5, three concrete subclasses of the abstract *TimeInstantRelation* class are defined: *CoincidenceRelation*, *PrecedenceRelation*, and *TimeIntervalMembership*.

CoincidenceRelation is a strong form of time instant relation: junction instants belonging to different time bases can be *coincident* (i.e., same time and same place). In modeling, coincidence has not necessarily this strict relativistic meaning. It may represent clock synchronizations or design choices, for instance. The coincidence relation must be symmetric and transitive. Moreover, we assume that any junction instant is coincident with itself, so that the coincidence relation is an equivalence relation over instants. A strong requirement is that adding coincidence does not introduce cyclic dependencies in the temporal ordering. In mathematical words, the set of instants quotiented by the coincidence relation must be a *partially ordered set*. For convenience, the coincidence relation is often represented in diagrams by linking pairs of coincident instants. The actual relation is obtained by computing the transitive closure of the relation. Figure 9.6 shows an example for a multiple time base made of three time bases. Junction instants a2 and b2 are coincident. So are b2 and c2. Even if not drawn in the picture, a2 and c2 are also coincident junction instants (by transitivity).

Figure 9.6 - Example of multiple time base with coincidences

PrecedenceRelation between junction instants from different time bases is a time instant relation weaker than coincidence. It expresses a directional dependency: a junction instant owned by a time base may precede or follow junction instants owned by other time bases.

A *time interval* on a time base is a convex set of junction instants owned by this time base. The convexity is the property that ensures that any junction instant between two junction instants of the interval is also in the interval. Two Boolean attributes specify whether the lower and upper bounds of the interval are in the interval or not. By default, the interval is closed on both boundaries. The bounds and the closure attributes must specify a non empty set of instants. The time interval is specified by its two bound junction instants. The *TimeIntervalMembership* is a relation that characterizes junction instants (members) which are either in the given time interval or are coincident with junction instants in this time interval.

9.2.2.2 Concrete time base relations

As explained in the previous section, time instant relations induce relations on time bases of a multiple time base. *Time base relations* are a higher level way to impose dependencies between junction instants. A time base relation specifies a set of time instant relations. As shown in Figure 9.7, for any two time bases A and B, one defines a relation A is *finer* than B (or B is *coarser* than A) if for each junction instant in B there exists one and only one coincident junction instant in A. This relation can be characterized by a mapping M from the coarser time base B to the finer time base A. This mapping is injective and order-preserving (i.e., if b1 and b2 are two junction instants of B, and b1 is before b2, then a1 = M(b1) and a2 = M(b2) are such that a1 is before a2 in time base A). Notice that the specific association between *DiscreteTimeBase* and *TimeBase* (Figure 9.3, page 71) represents a coarser/finer relationship: the coarser time base, which is discrete, results from a discretization of its covering time base (i.e., its *coveringTB* property), which is a dense time base.

Figure 9.7 - Example of time relations between two time bases

When the finer time base is also a discrete time base, more precise relations can be specified. For instance, the *k-finer* relation is defined as follows. A is *k-finer* than B for k integer, $k \geq 1$, if A is *finer* than B and for any two consecutive instants in B, there exist k-1 instants between the corresponding coincident instants in A. Figure 9.7 illustrates an example where $k=2$.

Predefined time base relations are proposed in the TimeStructureRelation Library of MARTE. The semantics of these relations is given in OCL.

9.2.3 The TimeAccesses package

In real technical systems, special devices, called clocks, are used to measure the progress of physical time. In MARTE we adopt a more general point of view: a clock is considered as a means to access to time, be it physical or logical. In the TimeAccesses package, we introduce the concepts of *Clock*, *TimeValue* and *DurationValue*. These concepts are introduced without any specific reference to physical time. Thus, they can be also applied to logical time. Clocks that refer to physical time will be considered as specialized clocks.

The TimeAccesses package is subdivided into four packages as shown in Figure 9.8:

- The Clocks package introduces a general concept of clock.
- The TimeValues package defines the concepts of time value and instant value.
- The DurationValues package defines the concept of duration value.

The ChronometricClocks package contains a specialization of the initial clock concept.

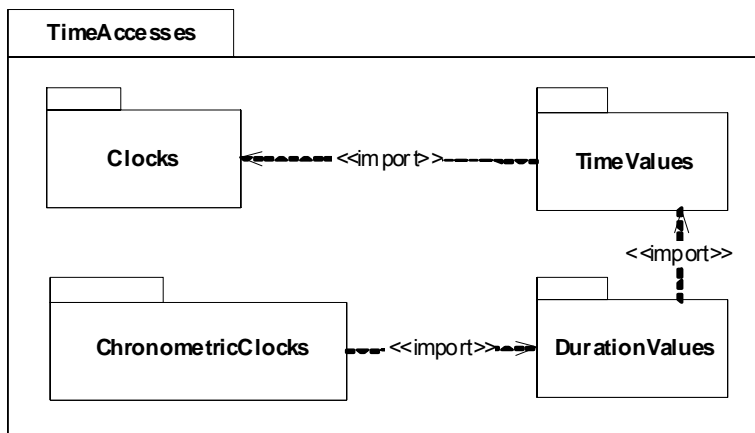

Figure 9.8 - Subpackage diagram of the TimeAccesses package

The “Value Specification Language” annex (Annex B) provides detailed definitions of abstract and concrete syntax for specifying time expressions in MARTE.

9.2.3.1 The Clocks package

As indicated in Figure 9.9, *Clock* is an abstract class. A concrete clock is either a logical clock or a chronometric clock. The latter is defined in another package (*ChronometricClocks* package on page 78).

A *Clock* refers to a discrete time base (its *timeBase*) and therefore indirectly to a set of junction instants. The *timeBase* discrete time base allows access to the time structure. A clock, whose nature is dense, may indirectly refer to a dense time base through the *coveringTB* property of its *base*.

A *Clock* accepts units (*acceptedUnits* property). Unit is defined in the *NFP_Nature* package. One of these accepted units is the *defaultUnit*. The default unit is the unit attached to the *currentTime* value. The *resolution* property specifies the readout granularity of the clock, expressed in *defaultUnit* unit. Its default value is 1.

The optional attribute *maximalValue* expresses the limited capability of usual clocks to represent arbitrary large instant values: the clock “rolls over” when the *currentTime* value gets at the *maximalValue*. Note that in this case *currentTime* maps on many junction instants.

A clock may own an event (*clockTick*). This event occurs at each change of the current time of the clock.

A *LogicalClock* is a concrete subclass of *Clock*. It may be defined by an event (*definingEvent* property); in this case, the logical clock ticks at each occurrence of the *definingEvent*. Logical time is usually counted in the number of ticks. So, *tick* is a predefined unit often used as the *defaultUnit* for a logical clock, and then the *resolution* of the clock is 1 (the default value).

Figure 9.9 - Clocks diagram of the time model

9.2.3.2 The TimeValues package

Figure 9.10 - TimeValues diagram of the time model

An application may use time in two ways: either as a reference to a time instant or as a time span. The *TimeValues* package deals with the first usage, while the *DurationValues* package addresses the latter.

Since the access to time is done through clocks, a *TimeValue* refers to a *Clock* (the *onClock* property). A *TimeValue* may also have a *unit* property. When *unit* is given, it must be in the *acceptedUnits* set of the *onClock*, and used instead of its *defaultUnit*. The attribute *nature* specifies whether the time values associated with the clock take their values in a dense or discrete domain. Since computers work with finite precision numbers, the distinction between discrete and dense sets is blurred by the limited precision of the representation: ultimately all values are discrete. Since the distinction between dense and discrete sets has a semantic meaning, we retain this distinction in the model, and we use “real” numbers for dense time values and integer numbers for discrete ones.

In the MARTE time model, logical clocks are always discrete, and their time values are integer numbers.

An *InstantValue*, which is a *TimeValue*, may refer to 0, 1, or many junction instants of a discrete time base. The multiple denotation of junction instants is due to the bounded nature of the representation of values. There may exist a folding of the time representation due to clock roll-over.

A *TimeIntervalValue* is defined as a pair of instant values and denotes 0 or many time intervals (many results from possible folding of the time representation). The *min InstantValue* refers to the lower instant of the time interval; the *max InstantValue* refers to the upper instant of the time interval. The closure properties of the interval are specified by the two Boolean attributes *isMinOpen* and *isMaxOpen*. By default, the interval is closed (i.e., it includes the min and max values).

When used in a time value specification, a time interval value indicates any time value in the interval.

The *TimeValue* class is abstract. It generalizes *InstantValue*, and *DurationValue*, which is introduced next.

9.2.3.3 The DurationValues package

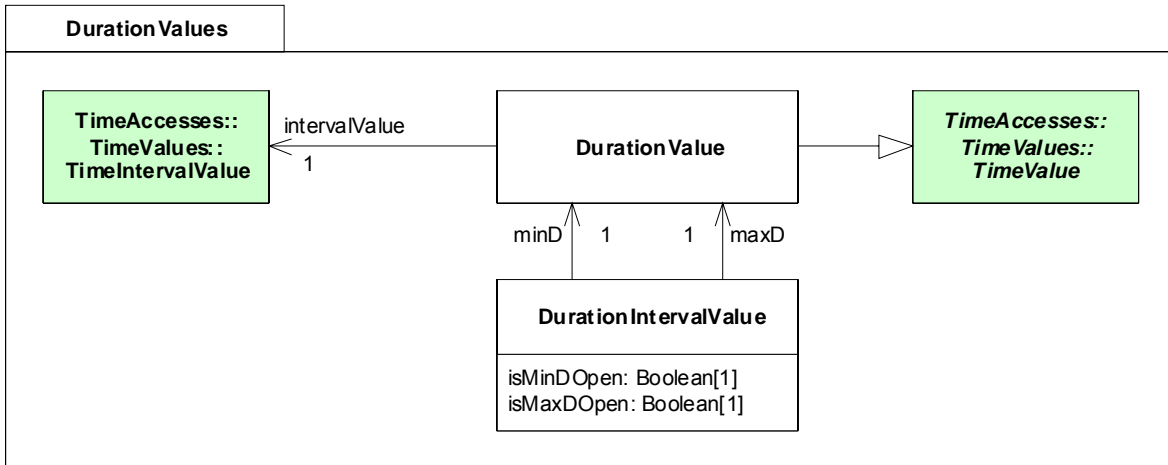

Figure 9.11 - DurationValues diagram of the time model

The *DurationValues* package introduces the concept of duration value (Figure 9.11). Duration is a “distance” between two instants. It characterizes the “extension” of a time interval. From the user’s point of view, a time interval is specified by a *TimeIntervalValue*. As explained in Section.9.2.3.2, a *TimeIntervalValue* may denote 0, 1 or many time intervals, due to possible clock roll-over. In the simple case when the clock has no defined *maximalValue*, the *DurationValue* of a *TimeIntervalValue* is defined by the difference between the *max* and *min* instant values of this time interval value. When the *maximalValue* property is defined, the *DurationValue* is defined as the difference modulo *maximalValue* between the *max* and *min* instant values of this time interval value.

A *DurationIntervalValue* is defined by a pair of duration values, which specifies an interval of values. When used in specification, a duration interval value indicates any duration value in the interval.

9.2.3.4 The ChronometricClocks package

Figure 9.12 - ChronometricClocks diagram of the time model

In Section 9.2.1, physical time has been characterized as a continuous and unbounded progression of physical instants. The progression of physical time is perceived through event occurrences. Some events are considered as better candidates to represent the (assumed) uniform progression of physical time. For instance, one may choose the period of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the cesium 133 atom (see the definition of the second time unit). Today, this is the best known reference. More conveniently, one considers cyclic events, whose occurrences are (more or less) periodic. Periodicity should be checked against the above mentioned best reference. Usually, periodic event generators are called clocks. We have already used this term in a broader sense: there is no reference to periodicity in clocks defined in Section 9.2.3. Therefore, we name *ChronometricClock* a clock that implicitly refers to physical time.

The *ChronometricClocks* package introduces the main concepts related to clocks bound to physical time (Figure 9.12). A chronometric clock provides quantitative information about time. Numerous non functional time-related properties can be defined for chronometric clocks. Only a few are presented below.

Figure 9.13 represents, in an informal way, the dependency of chronometric clocks on physical time. Physical time is modeled as a dense time base (the Real line). The instants of the discrete time base associated with a chronometric clock are coincident with physical instants regularly interspaced on the real line. In a chronometric clock, the resolution property is the duration value of physical time elapsed between two consecutive instants of this clock. Real chronometric clocks do not perfectly reflect evolution of physical time. Possible defects are characterized by non functional properties. For instance, *stability* is the ability for a clock to report consistent intervals of time. Stability is measured by derivatives of the clock rate, derivation against time or against environmental factors.

When many clocks are present in a system, other non functional time properties are considered. They are time-dependent pair-wise characteristics. Usually, one clock is taken as a reference clock against which the other clock is matched. When omitted, the reference clock is supposed to be an "almost perfect clock". Two clocks with the same rate may present an offset. This duration value may vary along time. The rate of change of the offset (i.e., its first derivative against time) between two clocks is called the skew. This skew itself may change over time. The derivative of the skew is called the *drift*.

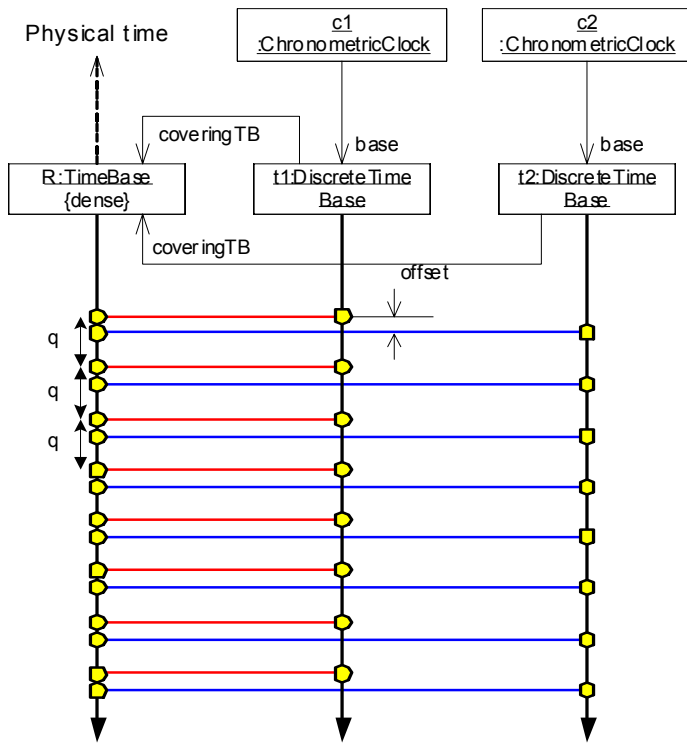

Figure 9.13 - Dependency example of chronometric clocks on physical time

9.2.4 The TimeRelatedEntities package

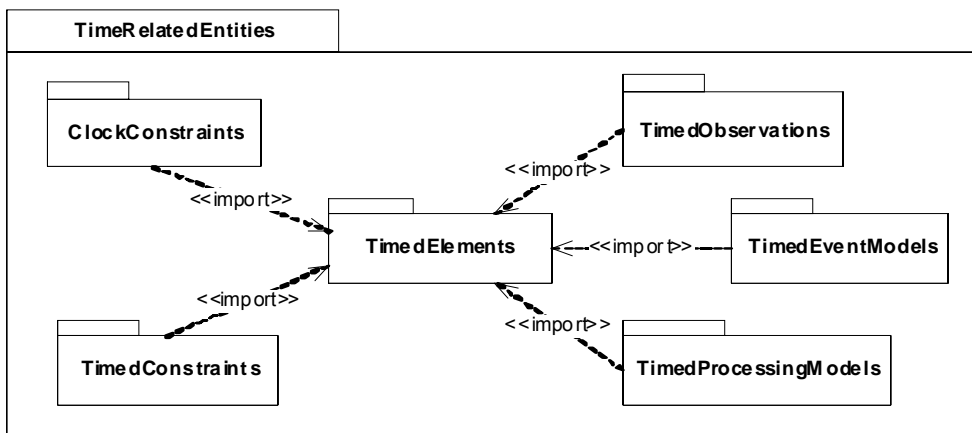

Figure 9.14 - Subpackages of the TimeEntities package

Time can be used for observation or for control. Typical examples of the first usage are observations of event occurrences in interactions diagrams. Time events triggering behaviors are examples of the second usage. MARTE proposes to explicitly relate events, actions, messages... to time. The TimeRelatedEntities package is subdivided into the following subpackages (Figure 9.14):

- the TimedElements package defines the key concept of TimedElement;
- the ClockConstraints package introduces constraints on clocks;
- the TimedObservations package provides concepts related to observation of timed entities;
- the TimedConstraint package specifies constraints on time-related observations;
- the TimedEventModels package deals with events whose occurrences are bound to time;
- the TimedProcessingModels package addresses executions bound to time.

9.2.4.1 The TimedElements package

Figure 9.15 - TimedElement diagram of the time model

A timed element, introduced in the TimedElements package (Figure 9.15), is a most general concept. TimedElement is an abstract class generalization of all other timed concepts. It associates a non empty set of clocks with a model element. The semantics of the association with clocks depends on the kind of timed element.

9.2.4.2 The ClockConstraints package

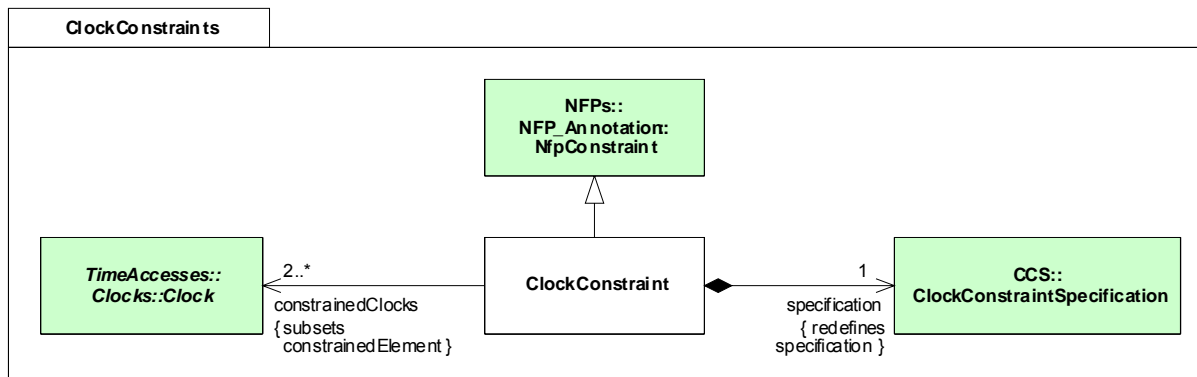

Figure 9.16 - ClockConstraints diagram of the time model

A clock constraint constrains two or more clocks. The specification of the constraint is expressed by a ClockConstraintSpecification. Clock constraint specifications are special value specifications described in Annex C (Clock Constraint Specification Language). An example of clock constraint is that two clocks are harmonic with one twice faster than the other.

9.2.4.3 The TimedObservations package

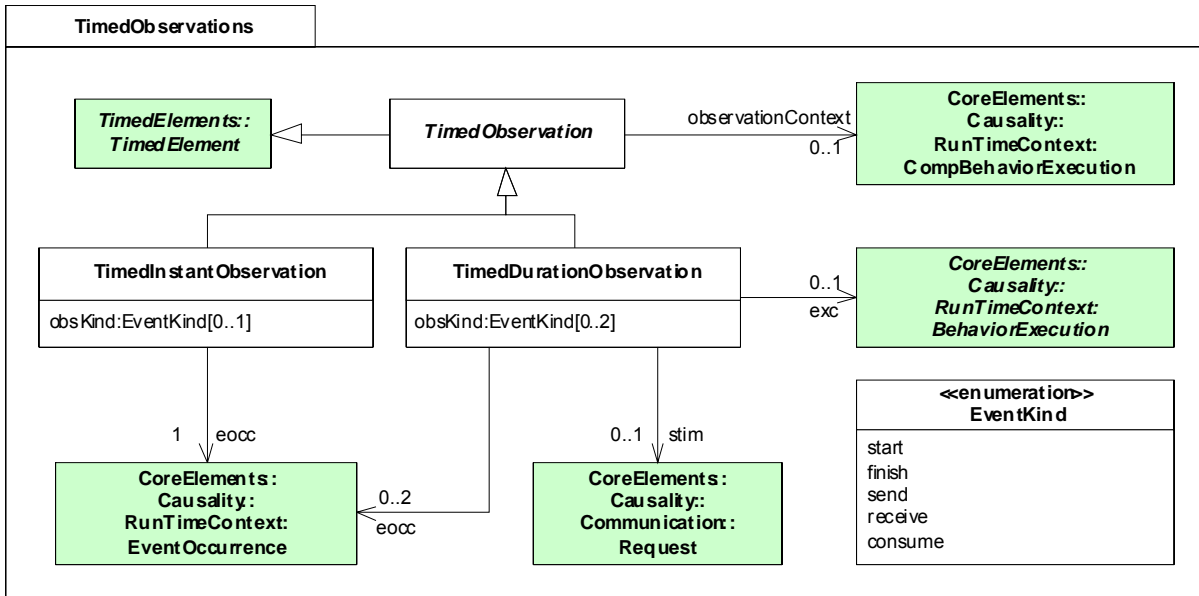

Figure 9.17 - TimedObservations diagram of the time model

TimedObservation is an abstract superclass of TimedInstantObservation and TimedDurationObservation. A TimedObservation is a TimedElement. As a TimedElement it has associated clocks, used for observing time. A TimedObservation is made in the runtime context of a (sub)system behavior execution (the observationContext property).

The enumeration literals of the EventKind enumeration allow the user to specify the kind of events considered in a TimedObservation. For a behavior, observed events can be either its start event or its finish event. For a Request, the possible events are its sending, its receipt or the start of its processing by the receiver.

A TimedInstantObservation denotes an instant in time, associated with an event occurrence (eocc property) and observed on a given clock. The obsKind property of the TimedInstantObservation may specify the kind of observed event.

A TimedDurationObservation denotes some interval of time, associated with execution, request, or two event occurrences, and observed on one clock or two clocks. The exc property associates the duration observation with a BehaviorExecution, which is an abstraction of CompBehaviorExecution and ActionExecution. The duration is the time elapsed between the occurrences of the start and the finish events of an execution of this BehaviorExecutionSpecification (i.e. a CompBehaviorExecution or an ActionExecution). The stim property associates the duration observation with a Request. A Message is a kind of Request. The duration can be observed between two of the three events associated with a request (its sending, its receipt or the start of its processing). The precise kind of event can be given by the obsKind attribute. Finally, a duration can be observed between two event occurrences (eocc property), not necessarily observed on the same clock.

9.2.4.4 The TimedConstraints package

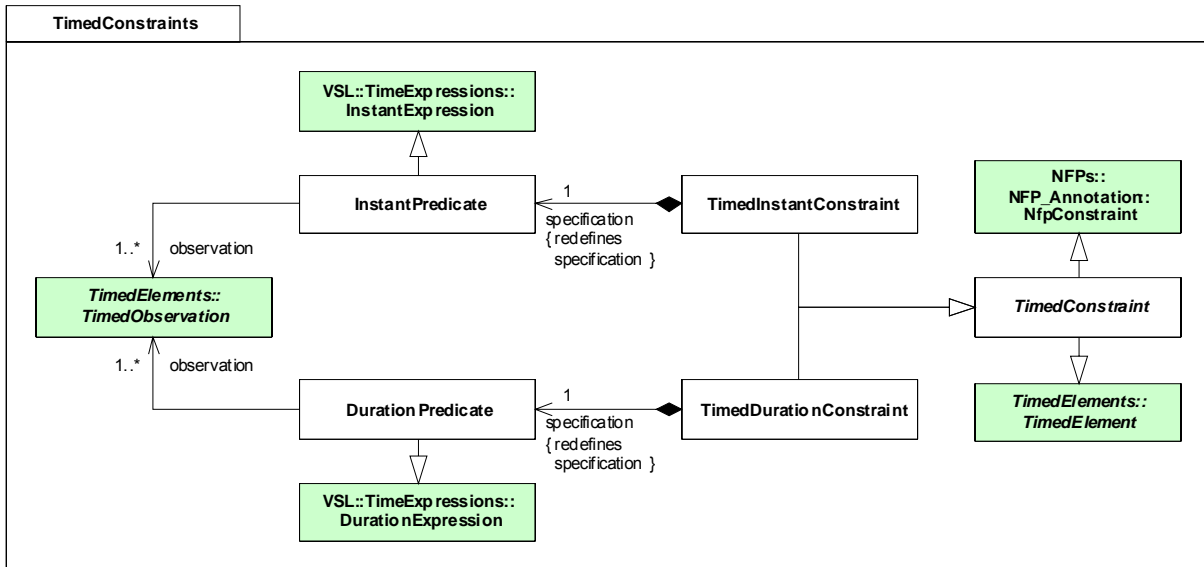

Figure 9.18 - TimedConstraints diagram of the time model

A TimedConstraint is a constraint imposed on the occurrence of an event (TimedInstantConstraint), or on the duration of some execution, or even on the temporal distance between two events (TimedDurationConstraint). The constraints are specified by predicates (InstantPredicate for instants and DurationPredicate for durations). A usual form of predicate is "the constrained instant value belongs to a given time interval value" or "the constrained duration value belongs to a given duration interval value". Instant and duration predicates contain usages of timed observations.

9.2.4.5 The TimedEventModels package

This package consists of two packages: TimeEventOccurrences and TimedEvents (Figure 9.19).

Figure 9.19 - The TimeEventModels package

The TimeEventOccurrences package

An event occurrence can be associated with time instants. MARTE introduces the concept of TimedEventOccurrence (Figure 9.20), which is both a TimedElement and an EventOccurrence. The at property specifies the instant value of this timed event occurrence on one of its clocks. Since a timed event occurrence may refer to several clocks (on property), several instant values (at property) are possible. Usually, there is one clock only, but several are allowed at least to cover the case of simultaneous occurrence set, introduced below.

This package also introduces the concept of `SimultaneousOccurrenceSet`. In the Causality Modeling chapter, an execution of a behavior may be caused by an event occurrence. In some situations, several events have to be considered as a whole because their collective effect cannot reduce to the serialization of their individual effects. The concept of `SimultaneousOccurrenceSet` is introduced to address this issue. A `SimultaneousOccurrenceSet` is an `EventOccurrence`, and as such, it can be the cause of a behavior execution. This concept is useful at design-time when different views of a same event, which have been introduced earlier, have to be merged into one event. It is also of common use in reactive synchronous modeling.

Figure 9.20 - `TimedEventOccurrences` diagram of the time model

The TimeEvents package

A `TimedEvent` is an event the occurrences of which are bound to clocks. A `TimedEvent` may have several occurrences. The `when` property specifies when the first occurrence occurs. The Boolean attribute `isRelative` specifies whether the time value is relative (the `when` property is a time duration value) or absolute (the `when` property is a time instant value). The `every` optional property permits repetitive occurrences of the timed event. When `every` is present, its value is the duration that separates the successive occurrences of the timed event. The number of occurrences can be limited by the `repetition` attribute. The time values are specified by CVS expressions. CVS (Clocked Value Specification) is defined in Annex C. A `CVS::ClockedValueSpecification` specifies a `TimeValue`, a `CVS::DurationValueSpecification` a `DurationValue`, and a `CVS::InstantValueSpecification` an `InstantValue`.

Figure 9.21 - TimedEvents diagram of the time model

9.2.4.6 The TimedProcessingModels package

This package consists of two packages: TimedExecutions and TimedProcessings.

Figure 9.22 - The TimedProcessingModels package

The TimedExecutions package

A TimedExecution is a TimedElement that is a specialization of the CoreElements::Causality::RunTimeContext::BehaviorExecution. As a TimedElement, a timed execution makes explicit reference to clocks.

Two instants values startInstant and finishInstant are associated with an execution and they correspond to the occurrence instants of its StartOccurrence and TerminationOccurrence, respectively. A DurationValue may also characterize an execution. Since a timed execution may refer to several clocks (on property), several time values are possible.

In the `CoreElements::Causality::RunTimeContext` package, `CompBehaviorExecution` and `ActionExecution` are concrete subclasses of `BehaviorExecution`, so that timed behavior executions and timed action executions also make explicit reference to clocks. A message transfer can also be assimilated to a timed execution (the sending instant being the `startInstant` of the communication and the receipt instant being its `finishInstant`). In what follows, `Behavior`, `Action`, and `Message` are collectively designated as timed processing, even if this assimilates a `Message` to its transfer.

Figure 9.23 - TimedBehaviorExecutions diagram of the time model

The TimedProcessings package

`TimedProcessing` (Figure 9.24) is a generic concept for modeling activities that have known start and finish times, or a known duration. In fact, two out of the three time values suffice to characterize a particular execution of the processing. For a timed message, start and finish events are respectively named as sending and receipt events.

A delay is a special kind of timed action that represents a null operation lasting for a given duration.

Figure 9.24 - TimedProcessings diagram of the time model

9.3 UML Representation

This section describes the UML extensions required to support the concepts defined in the Time Modeling domain view. Some concepts result in new stereotypes, others specialize stereotypes defined for NFPs modeling, and still others need no extensions at all. Most of the time-related stereotypes extend metaclasses from UML::Classes::Kernel, UML::CommonBehaviors and the SimpleTime package of CommonBehaviors.

9.3.1 Profile Diagrams

The Time profile depends on the NFPs profile as shown in Figure 9.25.

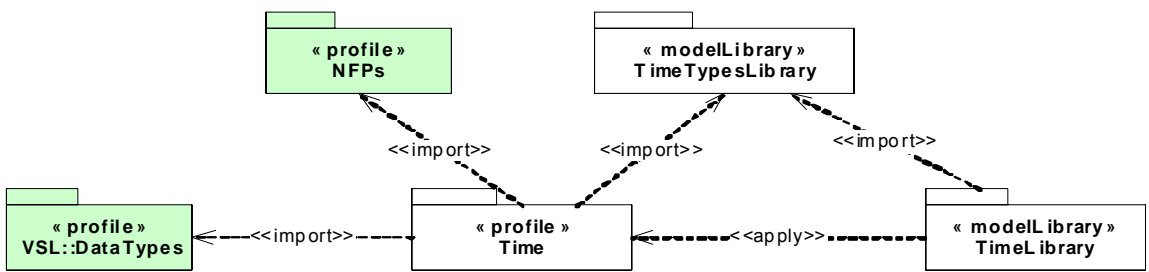

Figure 9.25 - Time profile dependencies diagram

For convenience, the Time profile is represented as a collection of diagrams. Each diagram gathers tightly related model elements. The actual Time profile consists of all these diagrams. The libraries are presented in Annex D.

9.3.1.1 TimedElement and Clock stereotypes

In the Time domain view, the concepts related to the time structure have been introduced in the BasicTimeModels and MultipleTimeModels packages. These concepts constitute the semantic domain of the Time model. The corresponding concepts in the UML view are ClockType and TimedDomain. The TimedDomain stereotype of the UML view maps to MultipleTimeBase and the ClockType stereotype maps to TimeBase.

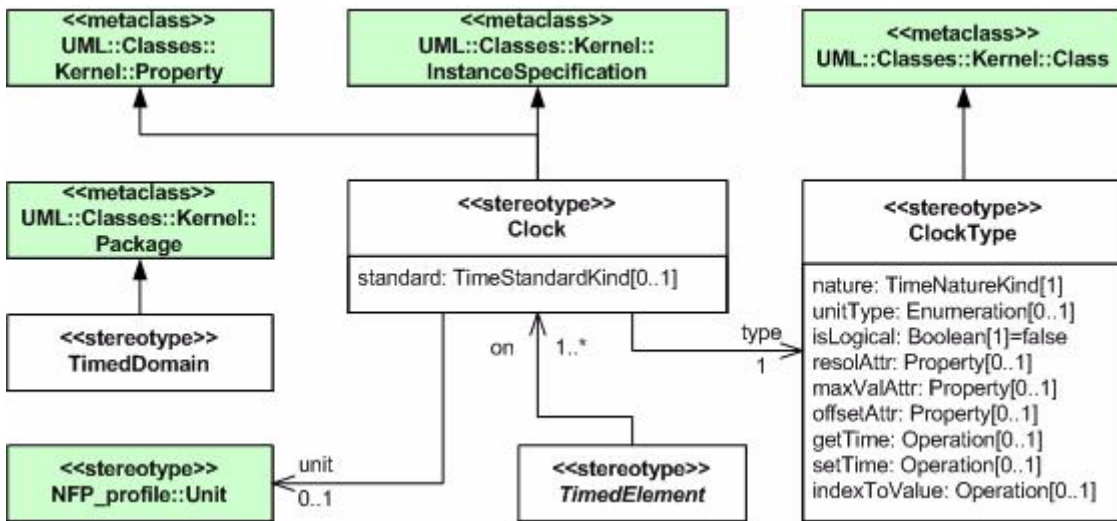

Figure 9.26 - UML extensions for Time modeling (1)

9.3.1.2 Timed value specification stereotypes

A TimedValueSpecification is the specification of a set of instances of time values. As a TimedElement, a TimedValueSpecification makes reference to Clocks. The optional interpretation property may force the interpretation of the value as duration or instant specification.

Figure 9.27 - UML extensions for Time modeling (2)

9.3.1.3 Constraint stereotypes

Time Modeling introduces two stereotypes specializing the NfpConstraint stereotype, which is itself an extension to the UML Constraint. TimedConstraint deals with constraints imposed on either instant value or on duration value, according to the value given to the interpretation attribute. ClockConstraint imposes dependency between clocks or between clock types. As TimedElement, both stereotypes refer to clocks. Additional OCL rules specify the constrained elements, the specification, and the context of the constraint. Note that VSL is convenient to express various timed constraints.

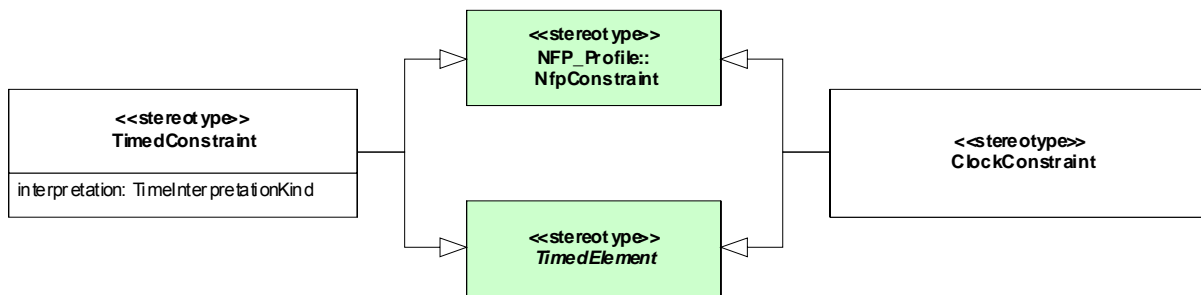

Figure 9.28 - UML extensions for Time modeling (3)

9.3.1.4 Observation stereotypes

TimedObservation is an abstract stereotype of TimedInstantObservation and TimedDurationObservation. It allows time expressions to refer to either in a common way. As a TimedElement, a TimedObservation makes reference to clocks. The optional obsKind attribute may specify the kind of the observed event(s). The Enumeration EventKind is part of the TimeTypesLibrary (Annex D.3.1).

Figure 9.29 - UML extensions for Time modeling (4)

9.3.1.5 Timed event stereotype

The TimedEvent stereotype represents Event whose occurrences are explicitly bound to clocks.

Figure 9.30 - UML extensions for Time modeling (5)

9.3.1.6 Timed processing stereotype

The TimedProcessing stereotype represents activities that have known start and finish times or a known duration, and whose instants and durations are explicitly bound to clocks.

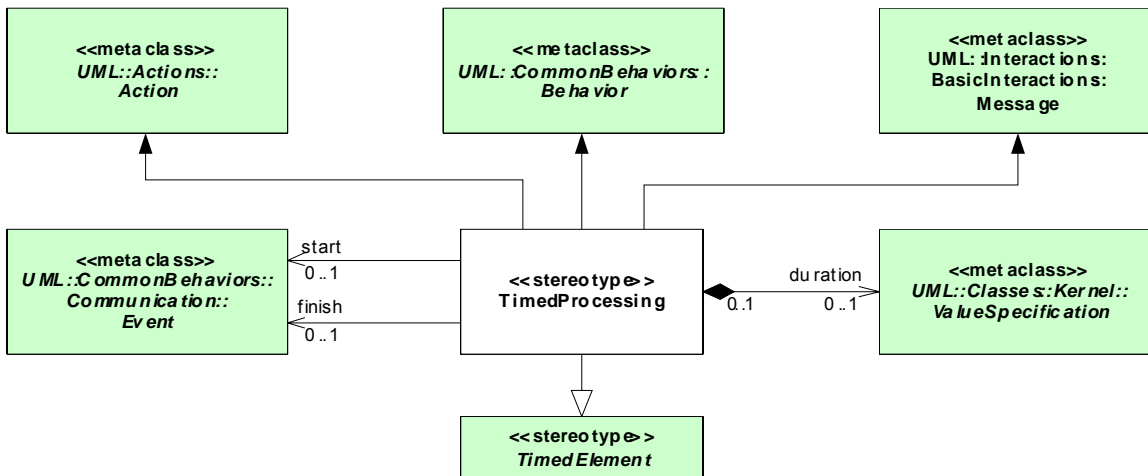

Figure 9.31 - UML extensions for Time modeling (6)

9.3.2 Profile elements description

9.3.2.1 Clock

The Clock stereotype maps the Clock domain element (section F.3.2) denoted in Annex F. It also relates to the ChronometricClock domain element (Section F.3.1).

A Clock is a model element that represents an instance of ClockType. A Clock gives access to time. A Clock exists in a TimedDomain. A Clock maps to a TimeBase in the semantic domain. The stereotype specifies the unit of the Clock. A Clock is also characterized by its resolution, and optionally by its offset (its initial instant value) and its maximal value. The values of these attributes are contained in the slots of the stereotyped InstanceSpecification.

A Clock can also be a stereotyped Property, so that it can be used in composite structure and interactions.

Extensions

- "Property (from UML::Classes::Kernel)
- InstanceSpecification (from UML::Classes::Kernel).

Generalizations

- None.

Associations

- type: ClockType[1]
specifies the ClockType whose this Clock is an instance.
- unit: NFPs::Unit[0..1]
defines the unit used by this Clock. If unit is not defined, then this Clock uses the anonymous tick unit. When defined, this unit must be of the unitType specified in the ClockType.

Attributes

- standard: TimeStandardKind[0..1]
references the system of time adopted by the clock. This property is not defined for a logical clock.

Constraints

[1] The owner of a class stereotyped by Clock must be a Package stereotyped by TimedDomain.

```
base_Class.owner.ocIsTypeOf(TimedDomain)
```

[2] The base_InstanceSpecification of the ClockInstanceSpecification must be an InstanceSpecification of the base_Class of its type property.

```
self.base_InstanceSpecification.classifier->includes(self.type.base_Class)
```

[3] The unit must be an ownedLiteral of the unitType enumeration of the ClockType.

```
self.unit->notEmpty( ) implies self.type.unitType.ownedLiteral->includes(self.unit)
```

[4] A logical clock does not have a defined standard.

```
self.type.isLogical implies self.standard->isEmpty( )
```

9.3.2.2 ClockConstraint

The ClockConstraint stereotype maps the ClockConstraint domain element (section F.3.3, p. 446) denoted in Annex F.

A ClockConstraint is a Constraint that imposes dependency between clocks or between clock types. A ClockConstraint refers to a set of clocks or clock types, and possibly to other model elements. The clocks in the constrained elements must belong to the on clock set of this ClockConstraint; the constrained clock types must be types of clocks in the on clock set. The specification of the constraint is usually an opaque expression using a dedicated language: CCSL (Clock Constraint Specification Language) defined in Annex C.

Extensions

- None

Generalizations

- NfpConstraint (from NFPs)
- TimedElement

Associations

- None

Attributes

- None

Constraints

[1] The constrained clocks are members of the on clock set of the ClockConstraint.

```
self.on->includesAll(self.base_Constraint.constrainedElement->select(c|c.oclIsTypeOf(Clock)))
```

[2] The constrained clock types are types of clock members of the on clock set of the ClockConstraint.

```
self.on->includesAll(self.base_Constraint.constrainedElement->select(c|c.oclIsTypeOf(ClockType).type))
```

9.3.2.3 ClockType

The ClockType stereotype maps the TimeBase domain element (section F.3.21) denoted in Annex F. It also related indirectly to Clock (section F.3.2) and ChronometricClock (section F.3.1).

A ClockType is a classifier for Clock. The attributes of the stereotype define the nature of the represented time (discrete or dense), the type of units, and whether its instances are logical clocks or chronometric clocks.

Extensions

- Class (from UML::Classes::Kernel)

Note – The ClockType stereotype the UML Class. This metaclass goes through several merge increments in the UML specification. Using UML::Classes::Kernel::Class does not preclude usage of Class from UML::StructuredClasses.

Generalizations

- None

Associations

- None

Attributes

- nature: TimeNatureKind [1]
specifies the nature dense or discrete of the time represented by this ClockType.
- unitType: UML::Classes::Kernel::Enumeration [0..1]
is the type of units supported by this ClockType.
- isLogical: Boolean [1] = false
specifies whether this ClockType reads a logical time or not. When isLogical is false, the ClockType reads a chronometric time, i.e., a time bound to physical time.

- **maxValAttr: Property [0..1]**
the maxValAttr property refers to a property of the base class. This property declares a read only attribute which determines the maximalValue of the associated Clock, value at which the clock rolls over. The maximal value is expressed with the clock's unit as a unity.
- **offsetAttr: Property [0..1]**
the offsetAttr property refers to a property of the base class. This property declares a read only attribute which determines the offset (initial instant) of the associated Clock. The offset is expressed with the clock's unit as a unity.
- **resolAttr: Property [0..1]**
the resolAttr property refers to a property of the base class. This property declares a read only attribute which determines the resolution of the associated Clock. The resolution is expressed with the clock's unit as a unity. When resolution is not defined, the granularity is arbitrarily small. This is the case for dense time.
- **getTime: UML::Classes::Kernel::Operation [0..1]**
the getTime property refers to an operation of the base class that returns the current time.
- **setTime: UML::Classes::Kernel::Operation [0..1]**
the setTime property refers to an operation of the base class that sets the current time.
- **indexToValue: UML::Classes::Kernel::Operation [0..1]**
the indexToValue property refers to an operation of the base class that yields the instant value associated with an instant specified by its index.

Constraints

- None

9.3.2.4 TimedConstraint

The TimedConstraint stereotype maps the TimedConstraint domain element (section F.3.25) denoted in Annex F. It also related indirectly to TimedInstantConstraint (section F.3.32) and TimedDurationConstraint (section F.3.26).

A TimedConstraint imposes constraints on either instant value or duration value associated with model elements bound to clocks. If interpretation is set to the enumeration literal instant, then the constraint is interpreted as a constraint on instant value. If interpretation is set to the enumeration literal duration, then the constraint is interpreted as a constraint on duration value. There is no other case. The specification of the constraint itself can be conveniently expressed in VSL.

Extensions

- None

Generalizations

- NfpConstraint (from NFPs)
- TimedElement

Associations

- None

Attributes

- **interpretation: TimeInterpretationKind [1]**
specifies whether the constraint applies to an instant value or to a duration value.

Constraints

[1] The owner of a constraint stereotyped by TimedConstraint must be a Package stereotyped by TimedDomain

`base_Constraint.owner.oclIsTypeOf(TimedDomain)`

[2] The interpretation property is either instant or duration

[3] `self.interpretation <> TimeInterpretationKind::any`

9.3.2.5 TimedDomain

The TimedDomain stereotype maps the MultipleTimeBase domain element (section F.3.17) denoted in Annex F.

A TimedDomain is a container of Clocks. Model elements of the TimeDomain may refer to Clocks to express that their behavior depends on time. A TimedDomain is also a context for a ClockConstraint. A TimedDomain may own nested TimedDomains. A TimedDomain maps to a MultipleTimeBase in the semantic domain.

Extensions

- Package (from UML::Classes::Kernel::Package)

Generalizations

- None

Associations

- None

Attributes

- None

Constraints

- None

9.3.2.6 TimedDurationObservation

The TimedDurationObservation stereotype maps the TimedDurationObservation domain element (section F.3.27) denoted in Annex F.

A TimedDurationObservation denotes some interval of time, observed on one or two clocks. The duration may be the time elapsed between the occurrences of the start and the finish events of an execution. The duration may also be the time elapsed between two of the three events associated with a message (its sending, its receipt, and the start of its processing by the receiver). More generally, the duration may be the time elapsed between the occurrences of two distinct events.

Extensions

- DurationObservation (from UML::CommonBehaviors::SimpleTime::DurationObservation).

Generalizations

- TimedObservation

Associations

- None

Attributes

- `obsKind: EventKind [0..2]` specifies the kind of the observed events.

Constraints

- None

9.3.2.7 TimedElement (abstract)

The `TimedElement` stereotype maps the `TimedElement` domain element (section F.3.28) denoted in Annex F.

The `TimedElement` stereotype is an abstract stereotype that does not extend UML meta classes. It stands for model elements referencing `Clocks`. Only concrete specializations of `TimedElement` can be applied.

Extensions

- None

Generalizations

- None

Associations

- `on: Clock [1..*]` references a set of `Clocks`.

Attributes

- None

Constraints

- None

9.3.2.8 TimedEvent

The `TimedEvent` stereotype maps the `TimedEvent` domain element (section F.3.29) denoted in Annex F. It also related indirectly to `TimedEventOccurrence` (section F.3.30).

The `TimedEvent` stereotype represents events whose occurrences are explicitly bound to a `Clock`. When this stereotype is applied to an `Event`, this `Event` specifies the first occurrence of this `Event` (`isRelative` and `when` properties). The `when` value is considered read on the `on Clock` of this `TimedEvent`, and with the unit of this `Clock`. The `every` property specifies the duration between successive occurrences, if any. The number of occurrences can be limited by the `repetition` property.

Extensions

- `TimeEvent` (from `CommonBehaviors::SimpleTime`)

Generalizations

- `TimedElement`

Associations

- every: UML::Classes::Kernel::ValueSpecification [0..1]
is an optional owned specification of the duration value between two successive occurrences of this TimedEvent. By default this duration is read on the on Clock of this TimedEvent. By applying the TimedValueSpecification stereotype to this ValueSpecification, another Clock can be chosen.

Attributes

- repetition: Integer[0..1]
is an optional repetition factor. When defined, repetition is the number of successive occurrences of the TimedEvent. Its absence is interpreted as an unbounded repetition.

Constraints

[1] A TimedEvent is bound to one Clock.

on->size() = 1

[2] The optional repetition property of a TimedEvent must be not defined when every is not defined.

every->isEmpty() implies repetition->isEmpty()

9.3.2.9 TimedInstantObservation

The TimedInstantObservation stereotype maps the TimedInstantObservation domain element (Section F.3.33) denoted in Annex F.

A TimedInstantObservation denotes an instant in time, associated with an event occurrence, and observed on a clock. The obsKind attribute may specify the kind of the observed event.

Extensions

- TimeObservation (from UML::CommonBehaviors::SimpleTime::TimeObservation)

Generalizations

- TimedObservation

Associations

- None

Attributes

- obsKind: EventKind [0..1] specifies the kind of the observed event.

Constraints

- None

9.3.2.10 TimedObservation (abstract)

The TimedObservation stereotype maps the TimedObservation domain element (section F.3.34, p. 460) denoted in Annex F.

TimedObservation is an abstract stereotype generalizing both stereotypes, TimedInstantObservation (Section 9.3.2.9) and TimedDurationObservation (section 9.3.2.6). It allows time expressions to refer to either in a common way. As a TimedElement, a TimedObservation makes reference to clocks.

Generalizations

- TimedElement

Associations

- None

Attributes

- None

Constraints

- None

9.3.2.11 TimedProcessing

The TimedProcessing stereotype maps the TimedProcessing domain element (section F.3.36) denoted in Annex F. It also related indirectly to TimedEventOccurrence (section F.3.30), TimedBehavior (section F.3.24), TimedAction (section F.3.23), TimedMessage (section F.3.34) and TimedExecution (section F.3.31).

The TimedProcessing stereotype represents activities that have known start and finish times or a known duration, and whose instants and durations are explicitly bound to Clocks.

Extensions

- Action (from UML::Actions)
- Behavior (from UML::CommonBehaviors)
- Message (from UML::Interactions::BasicInteractions)

Generalizations

- TimedElement

Associations

- duration: UML::Classes::Kernel::ValueSpecification [0..1]
is an optional owned specification of the duration of an execution for Action and Behavior, or the duration of a transmission for a Message. By default this duration is read on the on Clock of this TimedProcessing, if it is unique. By applying the TimedValueSpecification stereotype to this ValueSpecification, another Clock can be chosen.
- finish: UML::CommonBehaviors::Communication::Event [0..1]
the event whose occurrence determines the end of execution of the processing, for Action or Behavior; the receipt for a Message.
- start: UML::CommonBehaviors::Communication::Event [0..1]
the event whose occurrence determines the start of execution of the processing, for Action or Behavior; the sending for a Message.

Attributes

- None

Constraints

[1] Not all three properties are empty.

duration->notEmpty() or (start->notEmpty() and finish->notEmpty())

9.3.2.12 TimedValueSpecification

The TimedValueSpecification stereotype maps the TimeValue domain element (section F.3.44), InstantValue domain element (section F.3.14) and DurationValue domain element (section F.3.10) denoted in Annex F.

A TimedValueSpecification is the specification of a set of instances of time values. As a TimedElement, a TimedValueSpecification makes reference to Clocks. The optional interpretation property may force the interpretation of the value as duration or instant specification.

Extensions

- ValueSpecification (from UML::Classes::Kernel::ValueSpecification).

Generalizations

- TimedElement

Associations

- None

Attributes

- interpretation: TimeInterpretationKind[0..1] specifies whether the time values are instant values or duration values.

Constraints

- None

9.3.2.13 TimeInterpretationKind (from TimeTypesLibrary)

TimeInterpretationKind is an enumeration type that defines literals used to specify the way to interpret a time expression.

Literals

- duration indicates that the typed elements are time spans.
- instant indicates that the typed elements are instants.
- any indicates that the typed elements can be durations or instants.

9.3.2.14 TimeNatureKind (from TimeTypesLibrary)

TimeNatureKind is an enumeration type that defines literals used to specify the nature discrete or dense of a time value.

Literals

- discrete indicates that the typed elements are from a discrete set.

- dense indicates that the typed elements are from a dense set.

9.3.3 Examples

9.3.3.1 Chronometric clocks

The MARTE::TimeLibrary contains the description (IdealClock, a class stereotyped by ClockType) and an instance (idealClk) of an "ideal" clock. Starting with this clock, the user can define new chronometric clocks, as shown in Figure 9.32. These chronometric clocks may present deviations with respect to the ideal clock.

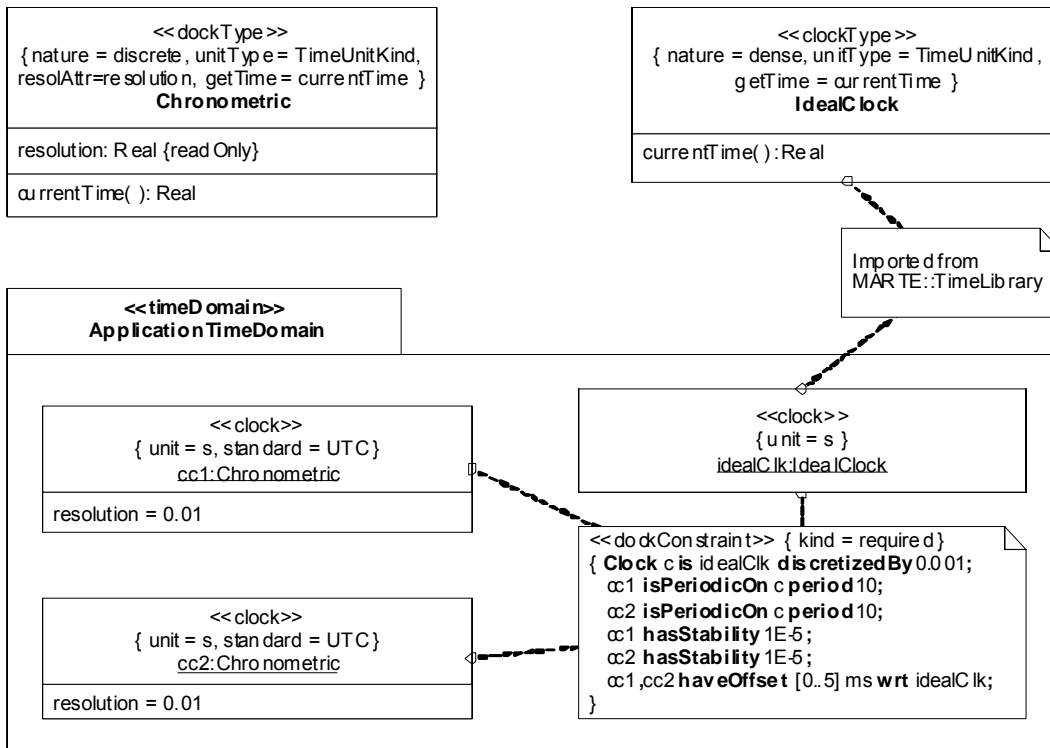

Figure 9.32 - Example of chronometric clocks

First, the user specifies a new ClockType: Chronometric, which is discrete, not logical (i.e., chronometric), and with a read only attribute (resolution).

Instances of clocks belong to timed domains. In this example only one time domain is considered, and it owns 3 clocks: idealClk, which is an instance of IdealClock, cc1 and cc2, which are two instances of Chronometric.

cc1 and cc2 use s (second) as their unit of time, have a resolution of 0.01 s and adopt the UTC system of time. The deviations of these clocks with respect to the ideal one are specified by a clock constraint. Clock constraints are expressed using a simple declarative language, called CCSL (Clock Constraint Specification Language), described in Annex C.

The clock constraint in Figure 9.32 imposes to cc1 and cc2 to be almost periodic (stability=10⁻⁵), with a period of 10 ms, and with an offset between the two clocks no greater than 5 ms. Note that the 10 ms period must be consistent with the given resolution (0.01 s = 10 ms). The first line, in the body of the constraint, declares a clock c, local to the constraint and not part of the system. c is defined as an ideal discrete clock whose resolution is 0.001 s = 1 ms. The other lines are constraints. Figure 9.33 represents a time structure that satisfies the given clock constraint.

Figure 9.33 - Instants of clocks cc1 and cc2

9.3.3.2 Logical clocks

In this simplified example, a processor executes the same code for several controllers (Figure 9.34). The processor is a Voltage Scaling processor: its frequency can be dynamically controlled. For simplicity, only two frequencies are considered: the frequency in the full power mode, and the frequency in the low power mode, which is half the former. The Boolean attribute inLowPower indicates the running mode of the processor. The control must be applied periodically (the period attribute of the Controller) by executing some code (pidCode which is an OpaqueBehavior). The behavior of the controller is specified by a state machine (ctrlBeh).

Figure 9.34 - Example of timed control

pidCode is a behavior that is executed in a fixed and known number of processor cycles. This can be modeled with a logical clock. To this end, the class Processor is stereotyped by ClockType. This mixture of physical time (period of activation) and logical time (execution duration expressed in processor cycles) is usual in control applications. Figure 9.35 represents instances and a clock constraint. The TimedDomain is not explicitly represented. There are two instances of Controller, with periods of activation equal to 1 and 2 ms, respectively. Each execution of pidCode takes 100 cycles of the processor, which is expressed by a TimedProcessing. The dependency between the processor cycle duration and the physical time is specified by a ClockConstraint. The constraint specification indicates that the local Clock c is a discrete clock with a period of 1 us (1E-6 s). Clock pr is derived from c. The period of pr is 20 us when running in the low power mode, and 10 us in the full power mode. The trigger of the transition labeled "after p" in the state machine, implicitly declares a TimeEvent with isRelative = true and when = p. This TimeEvent is stereotyped by TimedEvent with on = idealClk.

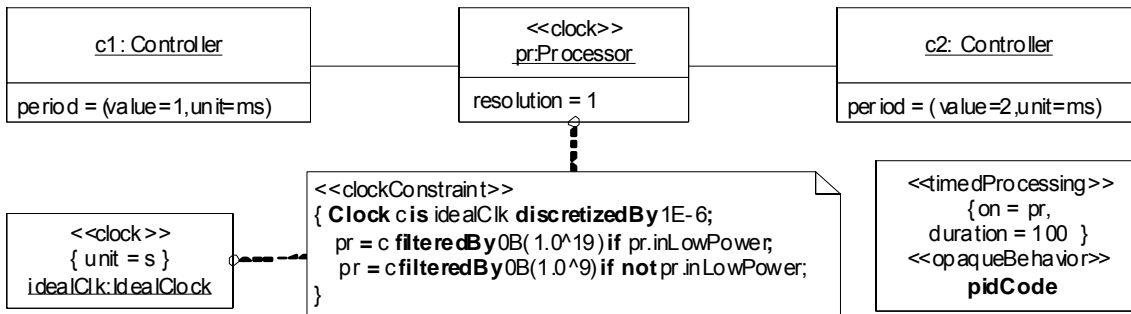

Figure 9.35 - Clocks and TimedProcessing

10 Generic Resource Modeling (GRM)

10.1 Overview

The objective of this package is to offer the concepts that are necessary to model a general platform for executing real-time embedded applications. The generic resource model (GRM) includes the features which are required for dealing with:

- Modeling of executing platforms at different level of details. The level of granularity needed for platform modeling depends on the concern motivating the description of the platform, as for example the type of the platform, the type of the application, or the type of analysis to be carried out on the model.
- Modeling of both "hardware" (e.g., memory units or physical communication channels) and "software" (e.g., real-time operating systems) platform.

Both sections 14.1 and 14.2 provide a specialization of this general resource model for software and hardware related platforms respectively.

Figure 10.1 describes the dependencies of the GRM package with other sub-packages of MARTE.

Figure 10.1 - Dependencies of the GeneralResourceModel (GRM) package

The different facets of the GRM are grouped in individual packages, following the structure shown in Figure 10.2:

- The ResourceCore package defines the basic elements and their relationships.
- The ResourceTypes package defines fundamental types of resources as well as the basic services that they provide.
- The ResourceManagement package defines specific management resources and their associated services.

Figure 10.2 - Architecture of the GeneralResourceModel (GRM) package

The purpose and contents of each sub-package are described in next sections.

10.2 Domain view

10.2.1 The ResourceCore package

The basic partitioning into classifiers and instances made in the Foundations package is used here to describe the nature of the basic resource elements, depicted in the class diagram in Figure 10.3. The central concept of the GRM is the notion of a Resource. A Resource represents a physically or logically persistent entity that offers one or more ResourceServices. Resources and its services are the available means to perform the expected duties and/or satisfy the requirements for which the system under consideration is aimed.

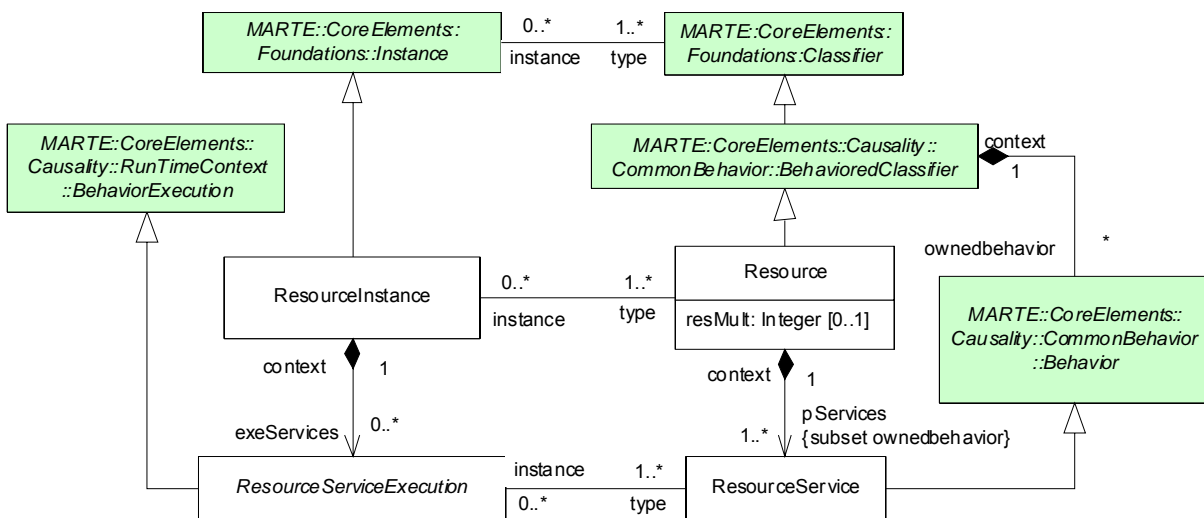

Figure 10.3 - Instance/Classifier nature of core resource elements

As shown in Figure 10.4, Resources and their respective instances are also kinds of AnnotatedElements, hence values of non-functional properties (NFPs) may be annotated on them. In particular, as a type of classifier, Resources may have NFPs declared on it. As it is also shown in Figure 10.4, besides the NFP specifications, a resource has an optional set of referenced clocks, normally only one, but more in general.

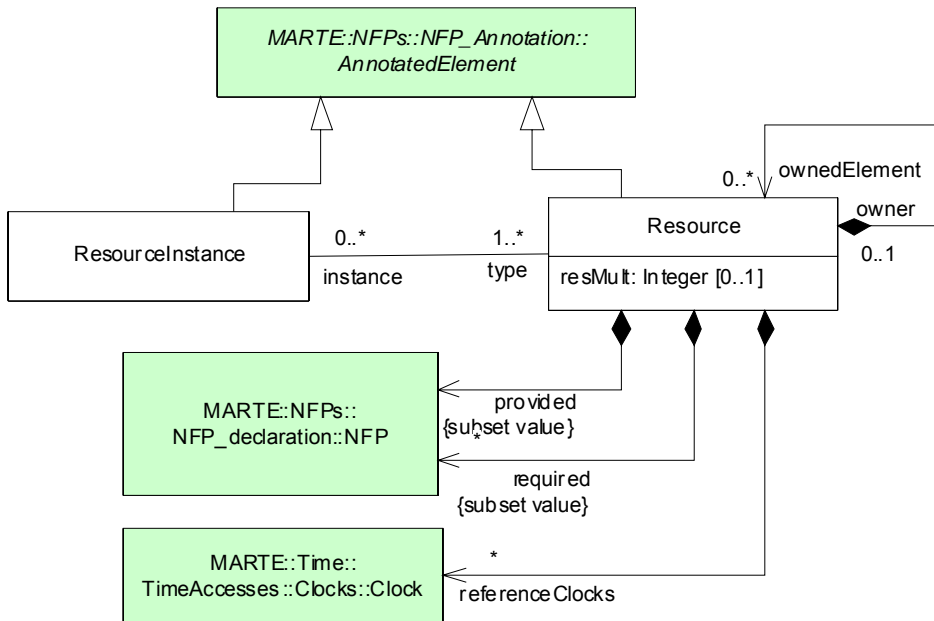

Figure 10.4 - NFP annotations and reference Clocks of a Resource

A second orthogonal aspect, which is also very important, is the necessity to differentiate between application and platform elements. These latter are considered either as resources or resource services. Resources are used to model the execution platform from a structural point of view, while the resource services supply the behavioral point of view. A resource may be structurally described in terms of its internal resources - this is represented by the "owner-ownedElement" association in Resource inherited from the ModelElement meta-class. For example, a processing resource may be refined as a processor connected to a memory through a bus, if such level of detail is of interest for the modeler or for the analysis method to be applied to the model.

The reference clock of a resource may be either a chronometric (i.e. "physical") clock or a logical clock. In any case, a clock is used as the reference unit for time related characteristics of the services provided by the resource. For example, considering chronometric clocks, the "processing time" associated with functions in a computation library may be expressed in terms of processor cycles rather than absolute time values. The reference clock (typically the processor clock) would then allow translating such values into physical times.

The optional attribute `resMult` (resource multiplicity) is used to express the limited nature of an aggregated multi elementary resource. When used it indicates the maximum number of instance of the elementary units of a particular type of resource that are available through its corresponding services.

`Resource` and `ResourceService`, as well as their corresponding instance-based concepts, `ResourceInstance` and `ResourceServiceExecution` respectively, may also provide and/or require non-functional properties. A `ResourceServiceExecution` is a kind of `BehaviorExecution` that represents a concrete instance of the realization of a service, in the context of the instance of a resource.

Figure 10.5 - Resource Reference, and ResourceAmount of the ResourceCore package

For convenience, as shown in Figure 10.5, two more abstract concepts are defined in this ResourceCore package:

- ResourceReference, to be used when modeling the dynamic creation of resources is required.
- ResourceAmount, representing a generic quantity of the "amount" provided by the resource. This may be mapped to any significant quantification of the resource, like memory units, utilization, power, etc.

A resource can be a “black box,” in which case only the provided services are visible, or a “white box,” in which case its internal structure, in terms of lower level resources, may be visible, and the services provided by the resource may be detailed based on collaborations of these lower level resources.

Note that in the case of the platform provider for example, it is up to the modeler to represent it as:

- One black box resource (e.g., a real-time operating system), which abstracts the hardware hence considered as internal elements.
- A collaboration between a software layer and a hardware layer.
- A collaboration between basically hardware elements. In this case, software features of the execution platform may be represented by overheads on raw hardware performance figure.
- Any combination of these previous approaches depending on the type of development and analysis method applied by the user.

The rationale for deciding if an element in the execution platform should be represented as a resource in the platform model is more related to its criticality in terms of real-time behavior, rather than to its software or hardware nature. Therefore, the interface (i.e., the set of services) provided by the execution platform as a whole may be much simpler than the API (Application Programming Interface) visible to the application software. Of course, a model library describing a given platform may provide several views, corresponding to different anticipated use cases for the platform.

As it occurs with classifiers, the execution platform may be represented as a hierarchical structure of resources.

10.2.2 The ResourceTypes Package

Figure 10.6 presents the basic resource types defined along with their specific attributes. Next a description of each of them is provided, including the interpretation of the resource base clock when necessary. A first characterization of resources can be done using the two additional attributes shown, isProtected and isActive. Each of the specialized kinds may be defined by considering the Boolean values for them. isProtected implies the necessity to arbitrate access to the resource or its services, while isActive means that it has its own course of action.

Figure 10.6 - Types of resources in the ResourceTypes package

- A StorageResource represents memory, and its capacity is expressed in number of elements; the size of an individual element in bits must be given. The reference clock corresponds to the pace at which data is updated in it, and hence it determines the time it takes to access to one individual memory element. The level of granularity in the amount of storage resources represented is up to the model designer. For example, if the storage resource represents a hard disk drive, the element could be a block or a sector, and the speed of the clock to access such element would be directly related to the disk rotation speed. The services provided by a storage resource are intended to move data between memory and a processing unit (which can be a computing resource or a communication endpoint).
- A TimingResource represents a hardware or software entity that is capable of following and evidencing the pace of time. It is defined as a kind of chronometric clock, and may represent a clock itself or a timer, in which case it acts according to the clock that it has as a reference. This concept is used to model the SPT TimingMechanism. According to the concrete kind of resource or timing mechanism that it represents, the referenced clock may be another chronometric clock or a logical clock, as defined in the time chapter. A timing resource may have concrete services for its management and operation. Figure 10.7 shows these services in the form of roles of associations with ResourceService in the model of timing resources.

Figure 10.7 - Timing resources

- A SynchResource represents the kind of protected resources that serve as the mechanisms used to arbitrate concurrent execution flows, and in particular the mutual exclusive access to shared resources. This general concept is further specialized inside the context of the GRM in the Scheduling package.
- A ComputingResource represents either virtual or physical processing devices capable of storing and executing program code. Hence its fundamental service is to compute, what in fact is to change the values of data without changing their location. It is active and protected.
- A ConcurrencyResource is a protected active resource that is capable of performing its associated flow of execution concurrently with others, all of which take their processing capacity from a potentially different protected active resource (eventually a ComputingResource). Concurrency may be physical or logical, when it is logical, the supplying processing resource needs to be arbitrated with a certain policy. This root concept is further specialized in the Scheduling package.
- A DeviceResource typically represents an external device that may require specific services in the platform for its usage and/or management. Active device resources may also be used to represent external specific purpose processing units, whose capabilities and responsibilities are somehow abstracted away. The implicit assumption is that their internal behaviour is not a relevant part of the model under consideration.
- As shown in Figure 10.8, two kinds of CommunicationResources are defined. A communication media has an attribute for defining the size of the elements transmitted; as expected, this definition is related to the resource base clock. For example, if the communication media represents a bus, and the clock is the bus speed, "element size" would be the width of the bus, in bits. If the communication media represents a layering of protocols, "element size" would be the

frame size of the uppermost protocol. It has also an attribute indicating the capacity of the communication element when it is applicable. For timing evaluations, it holds also the time it takes to transmit the element used as a communication quantum, usually called a packet, the size in bits of this quantum is described by the attribute elementSize. It may have also the specification of the time the communicationMedia is blocked and cannot transmit due to the transmission of one communication quantum, and the transmission mode available (simplex, half-duplex, or full-duplex). A communication endpoint acts as a terminal for connecting to a communication media, and it is characterized by the size of the packet handled by the endpoint. This size may or may not correspond to the media element size.

Figure 10.8 - Kinds of Communication resource in the ResourceTypeResourceTypes package

Concrete services provided by CommunicationEndPoint include the sending and receiving of data, as well as a notification service able to trigger an activity in the application. The fundamental service of a CommunicationMedia is to transport information (e.g. message of data) from one location to another location.

Figure 10.9 denotes some other basic services that may be provided by resources:

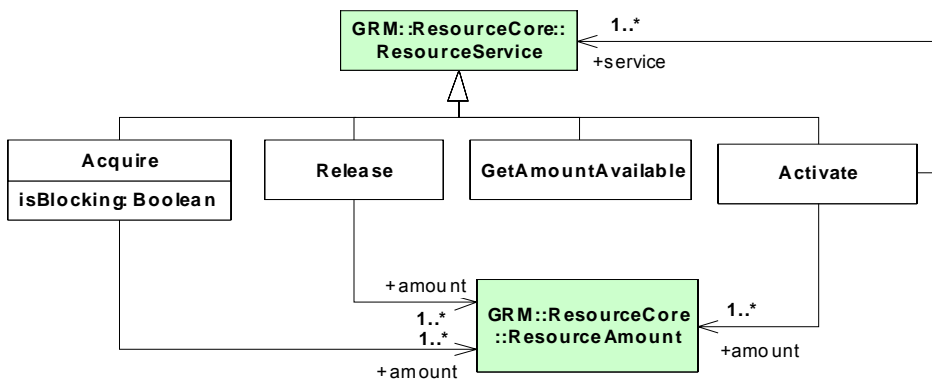

Figure 10.9 - Basic resource services of the ResourceTypeResourceTypes package

- Both Acquire and Release services correspond respectively to the allocation and de-allocation of some "amount" from the resource. For example, for a resource representing storage, the amount could be the memory size. As another example, a resource could represent a single element (maximum amount available is "1"), and acquire/release would be used to model mutual exclusive access.

- Activate corresponds to the application of a service on a given quantity. For example, activate a communication service with the amount of data to be transferred as a parameter.
- GetAmountAvailable returns the amount of the resource that is currently available.

The behavior shown by each service (acquire, release, activate, etc.) of a concrete resource that offers it, shall be described to the extent needed by the modeling concerns of that specific resource.

10.2.3 The ResourceManagement Package

The elements in this package serve for modeling various resource management services, such as those found in most operating systems. Figure 10.10 shows both types of resources that hold management services.

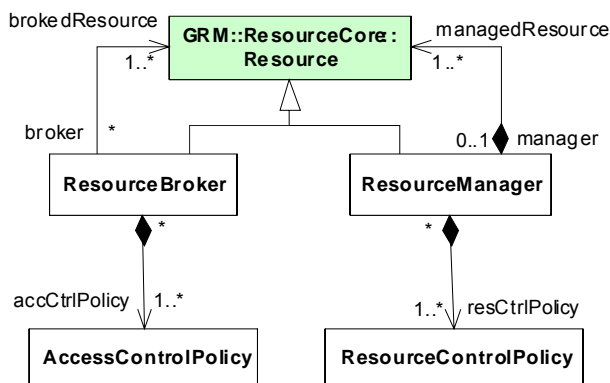

Figure 10.10 - Resource management

The ResourceBroker is a kind of resource that is responsible for allocation and de-allocation of a set of resource instances (or their services) to clients according to a specific access control policy. For example, a memory manager will allocate memory from a heap upon request from a client and also return it back into the heap once the client no longer needs it. The access control policy determines the criteria for determining and making effective the provision of resources, it can impose limitations on the prioritization of competing requests, or on the amount of memory provided to individual clients, etc.

On the other hand, the ResourceManager is responsible for creating, maintaining and deleting resources according to a resource control policy. For example, a buffer pool manager is responsible for creating a set of buffers from one or more chunks of heap memory. Once created and initialized, the resources are typically handed over to a resource broker. In most practical cases, the resource manager and the resource broker are the same entity. However, since this is not always true the two concepts are modeled separately (they can be easily combined by designating the same entity as serving both purposes).

10.2.4 The Scheduling Package

Scheduling is the way of arranging behavior at run-time. At this level of description a Scheduler is defined as a kind of ResourceBroker that brings access to its broke d ProcessingResource or resources following a certain scheduling policy. The concept of scheduling policy as it is presented here corresponds to the scheduling mechanism described in section 6.1.1 of SPT, since it refers specifically to the order to choose threads for execution. A ProcessingResource generalizes

the concepts of CommunicationMedia, ComputingResource, and active DeviceResource. It introduces an element that abstracts the fundamental capability of performing any behavior assigned to the active classifiers of the modeled system. Fractions of this capacity are brought to the SchedulableResources that require it.

A SchedulableResource is defined as a kind of ConcurrencyResource with logical concurrency. This means that it takes the processing capacity from another active protected resource, usually a ProcessingResource, and competes for it with others linked to the same scheduler under the basis of the concrete scheduling parameters that each SchedulableResource has associated. In the case of hierarchical scheduling, schedulers other than the main scheduler are represented by the SecondaryScheduler concept. This kind of schedulers do not receive processing capacity directly from a processing resource, instead they receive it from a SchedulableResource, which is in its turn effectively scheduled by another scheduler. These intermediate SchedulableResource, play the role of a virtual processing resource, conducting the fraction of capacity they receive from their host scheduler to its dependent secondaryScheduler.

Figure 10.11 shows the relationships between all these elements, as well as the various kinds of scheduling policies and the corresponding scheduling parameters.

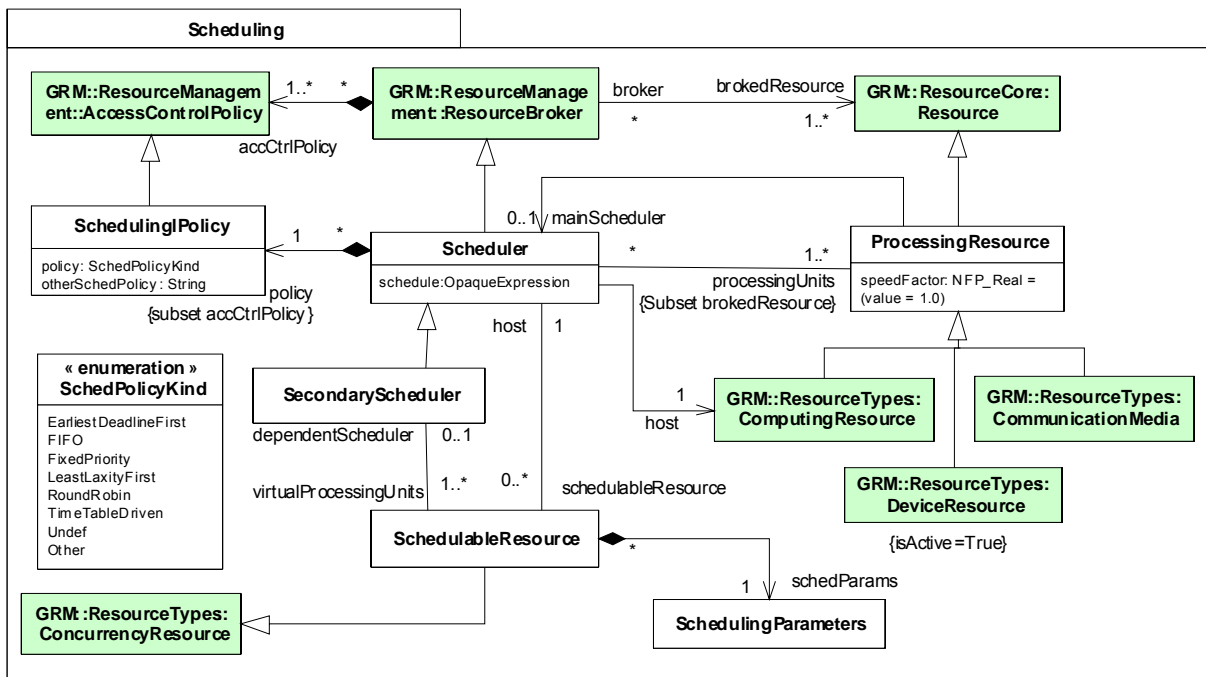

Figure 10.11 - The Scheduling package

When the executionBehaviors of concurrencyResources need to access common protected resources, the underlying scheduling mechanisms are typically implemented using some form of synchronization resource, (semaphore, mutex, etc.) with a protecting protocol to avoid priority inversions. Other solutions avoid this concurrency issue by creating specific schedules which order the access in advance. Whichever mechanism is used, the pertinent abstraction at this level of specification requires at least the identification of the common resource, its protecting mechanism, and the associated protocol; this is what the MutualExclusionResource defines. Figure 10.12 shows this element. Its associated protocol, represented by MutualExclusiveProtocol, is derived from the policy associated to the scheduler that manages it, and the parameters required by the protocol are represented by the ProtectionParameters element.

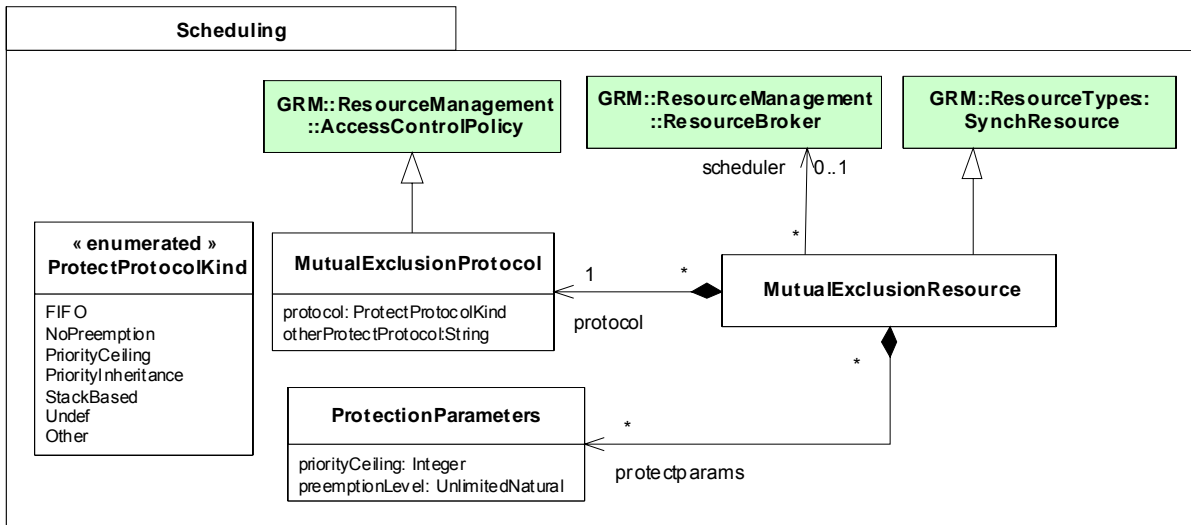

Figure 10.12 - The MutualExclusionResources in the Scheduling Package

10.2.5 The ResourceUsage Package

When resources are used, their usage may consume part of the "amount" provided by the resource. Taking into account these usages when reasoning about the system operation, is a central task in the evaluation of its feasibility. Figure 10.13 shows the model of a ResourceUsage, it links resources with concrete demands of usage over them. The concept of UsageDemand represents the dynamic mechanism that effectively requires the usage of the resource. Two general forms of usage are defined the StaticUsage and the DynamicUsage, each used according to the specific needs of the model. A few concrete forms of usage are defined at this level of specification under the concept of UsageTypedAmount; those are aimed to represent the consumption or temporary usage of memory, the time taken from a CPU, the energy from a power supply and the number of bytes to be sent through a network.

Figure 10.13 - Resource usage

10.3 UML Representation

This section describes the UML extensions provided to support the concepts defined in the presented domain view. The stereotypes here provided are generic and may be used at different levels of specification.

In order to get the maximum flexibility in the ways of applying the proposed stereotypes, most of the UML elements extended, are extended by the generic stereotype Resource. Then, through inheritance the large majority of stereotypes in GRM may extend elements like Property, InstanceSpecification, Classifier, Lifeline, and ConnectableElement. In particular, they might be applied for example to Classifiers, as well as to InstanceSpecifications of those very same Classifiers. In this case it is worth to consider the rules describe in section 7.3 for the usage of a stereotype in such situation. According to this rule when a stereotype is applied on an instance, the value of the attributes not explicitly assigned in the annotation of the instance are taken in principle from the defaults in the profile stereotype definition, but they might have to be taken from the annotation of the same stereotype on its corresponding classifier, which may have overwrote them, making effective with it the classifier nature of the annotation.

10.3.1 Profile Diagrams

The UML extensions proposed for the modeling of resources at this level of specification are provided in the MARTe::GRM profile and the MARTe::MARTe_Library::GRM_BasicTypes model library. They are shown in separate figures for convenience.

Figure 10.14 shows the stereotypes defined for the root concepts defined for the modeling of resources. Figure 10.16 shows the relationships between stereotypes defined for scheduling. Figure 10.17 shows the UML elements that may be extended with the GrService stereotype. And Figure 10.19 shows for convenience the model library that collects all the utilitarian types defined for the GRM profile and which is formally presented in Annex D.

The MARTE::GRM package (stereotyped as profile) defines how the elements of the domain model extend metaclasses of the UML metamodel. All the stereotypes defined in the GRM profile are then listed and described in alphabetical order. The semantic descriptions of the concepts that these stereotypes represent are provided along Section 10.2 on page 99. And the detailed descriptions of their corresponding concepts in the domain view are presented in Annex F in page 428. Finally the elements in the GRM_Basic_Types model library are also described in alphabetical order.

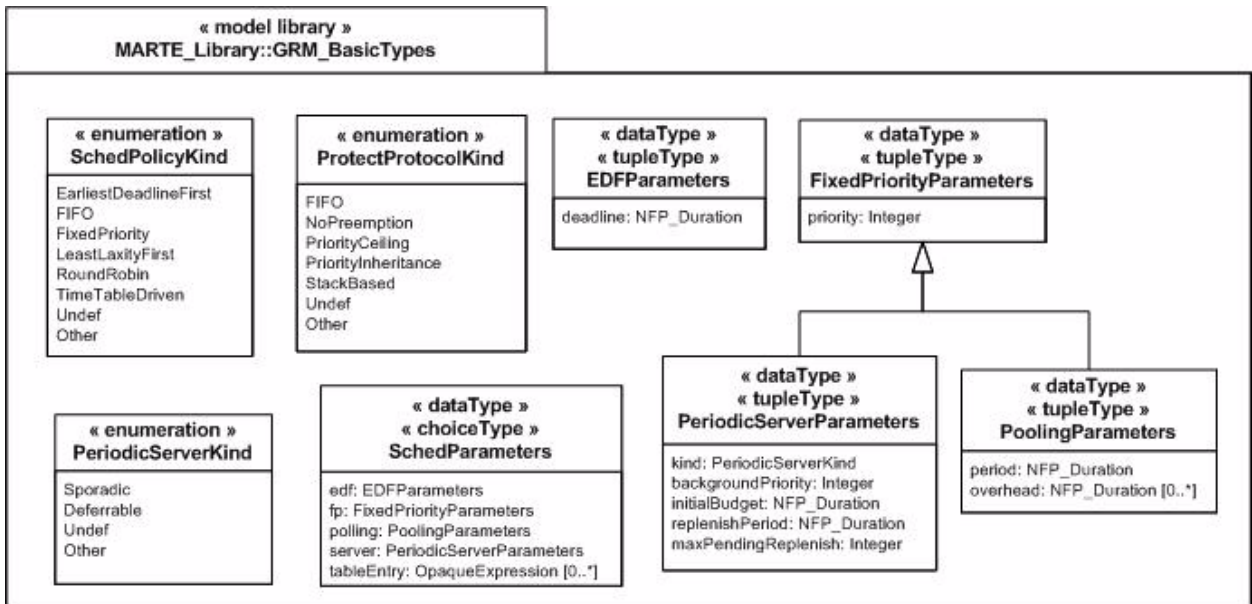

Figure 10.19 - Model library defining types used in the GRM profile (extract of Annex D)

10.3.2 Profile Elements Description

10.3.2.1 Acquire

The Acquire stereotype maps the Acquire domain element (section F.4.3) denoted in Annex F.

At this level of specification the amount to acquire is by default one and refers to the owner protected resource.

Extensions

- None.

Generalizations

- GrService.

Attributes

- isBlocking: Boolean [0..1]
if true it indicates that any attempt to acquire the resource may result in a blocking situation if it is not available. If false it indicates that the unavailability of the protected resource will not block the caller but it will be returned as part of the service results instead.

Associations

- None.

Constraints

- [1] The resource that owns the service must be a protected resource (i.e., its attribute isProtected must be true).

10.3.2.2 ClockResource

The ClockResource stereotype maps the ClockResource domain element (section F.4.5) denoted in Annex F.

Extensions

- None

Generalizations

- TimingResource

Attributes

- None

Associations

- None

Constraints

- None

10.3.2.3 CommunicationEndPoint

The CommunicationEndPoint stereotype maps the CommunicationEndPoint domain element (section F.4.6) denoted in Annex F.

Extensions

- None

Generalizations

- Resource

Attributes

- packetSize: Integer[0..1] the size of the packet handled by the endpoint.

Associations

- None

Constraints

- None

10.3.2.4 CommunicationMedia

The CommunicationMedia stereotype maps the CommunicationMedia domain element (section F.4.7) denoted in Annex F.

Extensions

- Connector (from UML::CompositeStructures::InternalStructures).

Generalizations

- ProcessingResource

Attributes

- elementSize: Integer[0..1] characterizes the size of the elements to be transmitted.
- capacity: NFP_DataTxRate [0..1] capacity of the communication element when applicablelink.
- packetT: NFP_Duration [0..1] time to transmit the element used as a communication quantum, usually called a packet, the size in bits of this quantum is described by the attribute elementSize.
- blockT: NFP_Duration [0..1] time the communicationMedia is blocked and cannot transmit due to the transmission of one communication quantum.
- transmMode: MARTE_Library::MARTE_DataTypes::TransmModeKind [0..1] defines the transmission mode, one of the following values: {simplex, half-duplex, full-duplex}.

Associations

- None

Constraints

- None

10.3.2.5 ComputingResource

The ComputingResource stereotype maps the ComputingResource domain element (section F.4.9) denoted in Annex F.

Extensions

- None

Generalizations

- ProcessingResource

Attributes

- None

Associations

- None

Constraints

[1] The attribute isActive inherited from Resource is always true.

10.3.2.6 ConcurrencyResource

The ConcurrencyResource stereotype maps the ConcurrencyResource domain element (section F.4.10) denoted in Annex F.

Extensions

- None

Generalizations

- Resource

Attributes

- None

Associations

- None

Constraints

- None

10.3.2.7 DeviceResource

The DeviceResource stereotype maps the DeviceResource domain element (section F.4.11) denoted in Annex F.

When it is active it can be considered as an external processing resource whose responsibilities will not be described in detailed in the model under consideration.

Extensions

- None

Generalization

- Resource

Attributes

- None

Associations

- None

Constraints

- None

10.3.2.8 GrService

The GrService stereotype maps the ResourceService domain element (section F.4.26) denoted in Annex F.

It is a very general concept that helps in the definition of generic resource models able for further refinement.

Extensions

- Behavior (from UML::CommonBehaviors::BasicBehaviors)
- BehaviorExecutionSpecification (from UML::Interactions::BasicInteractions)

- BehavioralFeature (from UML::Classes::Kernel)
- Collaboration (from UML::CompositeStructures::Collaborations)
- CollaborationUse (from UML::CompositeStructures::Collaborations)

Generalizations

- None

Attributes

- owner: Resource [0..1] refers to the resource that owns the represented service.

Associations

- None

Constraints

- None

10.3.2.9 MutualExclusionResource

The MutualExclusionResource stereotype maps the MutualExclusionResource domain element (section F.4.15) denoted in Annex F.

Extensions

- None

Generalizations

- Resource

Attributes

- ceiling: Integer [0..1]
determines the concrete parameter used to characterize the protection access protocol, it is used for the PriorityCeiling and the StackBased protocols. For the latter only positive values are to be used. It holds the concept of ProtectionParameters of the domain model.
- otherProtectProtocol: String [0..1]
is used to annotate a protocol that is not included among the values of the ProtectProtocolKind enumerated type.
- protectKind: ProtectProtocolKind [0..1]=PriorityInheritance
determines the type of protection protocol used to access the resource.

Associations

- scheduler: Scheduler [0..1] refers to the scheduler that will implement the protection protocol.

Constraints

[1] The attribute isProtected inherited from Resource is always true.

[2] The scheduling policy of the scheduler must be compatible to the kind of protectKind given to the MutualExclusionResource.

10.3.2.10 ProcessingResource

The ProcessingResource stereotype maps the ProcessingResource domain element (section F.4.16) denoted in Annex F.

It is an active, protected, executing-type resource that is allocated to the execution of schedulable resources, and hence any actions that use those schedulable resources to execute. In general, they abstract the processing capabilities of a computing resource, a communication media or an active external device.

Extensions

- None

Generalizations

- Resource

Attributes

- speedFactor: Real [0..1] = (value=1.0)
is a relative factor for annotating the processing speed expressed as a ratio to the speed of the reference processingResource for the system under consideration. The amount of resource usages specified for the entities in further usage models (like execution times for schedulability) assume a normative value of 1.0, what means that they have been measured or estimated either in respect to the reference system platform or directly over the platform used if it has speedFactor equal to 1.0.

Associations

- mainScheduler: Scheduler [0..1] is the scheduler that controls the access to its processing capacity.

Constraints

- None

10.3.2.11 Release

The Release stereotype maps the Release domain element (section F.4.19) denoted in Annex F.

At this level of specification the amount release is by default one and refers to the owner protected resource.

Extensions

- None

Generalizations

- GrService

Attributes

- None

Associations

- None

Constraints

[1] The resource that owns the service must be a protected resource (i.e., its attribute `isProtected` must be true).

10.3.2.12 Resource

The Resource stereotype maps both Resource (section F.4.20) and ResourceInstance domain elements (section F.4.23) denoted in Annex F.

It is provided for further refinement and for the representation of generic resources from a holistic system wide perspective. The nature of the concrete element extended defines the domain concept that it represents.

Extensions

- InstanceSpecification (from UML::Classes::Kernel)
- Classifier (from UML::Classes::Kernel)
- Property (from UML::Classes::Kernel)
- Lifeline (from UML::Interactions::BasicInteractions)
- ConnectableElement (from UML::CompositeStructures::InternalStructures)

Generalizations

- None

Attributes

- `resMult`: Integer [0..1] = 1
indicates the multiplicity of a resource. For a classifier it may specify the maximum number of instances of the resource considered as available. By default only one instance is available.
- `isProtected`: Boolean [0..1]
if true it indicates that the access to the resource is protected by some kind of brokeringResource.
- `isActive`: Boolean [0..1]
if true it indicates that the resource has an initial behavior associated that allows it to possibly perform its services autonomously or by the triggering and animation of behaviors on others.

Associations

- None

Constraints

- None

10.3.2.13 ResourceUsage

The ResourceUsage stereotype maps both ResourceUsage (section F.4.27) and UsageTypedAmount (section F.4.40) domain elements denoted in Annex F.

Extensions

- NamedElement (from UML::Classes::Kernel)

Generalizations

- None

Attributes

- `execTime`: NFP_Duration {ordered} [*]
time that the resource is in use due to the usage.
- `msgSize`: NFP_DataSize {ordered} [*]
amount of data transmitted by the resource.
- `allocatedMemory`: NFP_DataSize {ordered} [*]
amount of memory that is demanded from or returned to the resource. It may be a positive or negative value
- `usedMemory`: NFP_DataSize {ordered} [*]
amount of memory that will be used from a resource but that will be immediately returned, and hence should be available while the usage is in course. This may be used to specify the required free space in the stack for example.
- `powerPeak`:NFP_Power {ordered} [*]
power that should be available from the resource for its usage.
- `energy`:NFP_Energy {ordered} [*]
amount of energy that will be permanently consumed from a resource due to the usage.

Associations

- `usedResources`: Resource [0..*] {ordered}
list of resources that are used.
- `subUsages`: ResourceUsage {ordered} [0..*]
list of resourceUsages used to complement the description of the resourceUsage and generate composite descriptions.

Constraints

- [1] To consider the ResourceUsage fully specified, if the list `usedResources` is empty the list `subUsages` should not be empty and viceversa. Further refinements of ResoureUsage may define additional attributes that may bring implicit elements into the `usedResources` list.
- [2] If the list `usedResources` has only one element, all the optional lists of attributes (`execTime`, `msgSize`, `allocatedMemory`, `usedMemory`, `powerPeak` and `energy`) refer to this unique Resource and at least one of them must be present.
- [3] If the list `usedResources` has more than one element, all of the optional lists of attributes (`execTime`, `msgSize`, `allocatedMemory`, `usedMemory`, `powerPeak`, and `energy`) that are present, must have that number of elements, and they will be considered to match one to one.
- [4] If the list `subUsages` is not empty, and any of the optional lists of attributes (`execTime`, `packetSize`, `allocatedMemory`, `usedMemory`, `powerPeak`, and `energy`) is present, then more than one annotation for the same resource and kind of usage may be expressed. In this case, if the annotations have also the same source and statistical qualifiers they will be considered in conflict, and hence the ResourceUsage inconsistent.

10.3.2.14 SchedulableResource

The SchedulableResource stereotype maps the SchedulableResource domain element (section F.4.29, p. 478) denoted in Annex F.

It is an active resource able to perform actions using the processing capacity brought from a processing resource by the scheduler that manages it.

Extensions

- None

Generalizations

- Resource

Attributes

- schedParams: SchedParameters [0..*] parameters used to compete for processing capacity.

Associations

- dependentScheduler: SecondaryScheduler [0..1]
this scheduler takes its capacity from the schedulable resource, and in its turn shares it among its nested served schedulable resources.
- host: Scheduler [0..1]
is the scheduler that controls the processing capacity that will be shared among the demanding schedulable resources.

Constraints

- [1] The policy used by the scheduler (host) must be compatible with the scheduling parameters (schedparams) of the schedulable resource.

10.3.2.15 Scheduler

The Scheduler stereotype maps the Scheduler domain element (section F.4.30, p. 479) denoted in Annex F.

Extensions

- None

Generalizations

- Resource

Attributes

- isPreemptible: Boolean [0..1] = true
qualifies the capacity of the scheduler for preempting schedulable resources once the access to the processing capacity has been granted upon the arrival of a new situation where a different schedulabe resource has to execute.
- otherSchedPolicy: String
is used to annotate a scheduling policy that is not included among the values of the schedPolicyKind enumerated type.

- **schedPolicy:** schedPolicyKind [0..1] = fixedPriority
scheduling policy implemented by the scheduler.
- **schedule:** OpaqueExpression [0..1]
is the concrete schedule to use in the case of time table driven strategies. The format for expressing the times for activation and suspension, the cycle time as well as the number and identification of schedulable resources is user dependent.

Associations

- **host:** ComputingResource [0..1]
refers to the computing resource on which the scheduler runs. It may be or not the same computing resource whose processing capacity it will control and share among the demanding scedulable resources.
- **processingUnits:** ProcessingResources [0..*]
list of ProcessingResources whose processing capacity is shared by the scheduler among the schedulableResources it has associated.
- **protectedSharedResources:** MutualExclusionResource[0..*]
list of the MutualExclusionResources to which access must be protected using the corresponding protocol.
- **schedulableResources:** SchedulableResource [0..*]
list of schedulable resources that demand processing capacity from the scheduler.

Constraints

- [1] The scheduling policy of the scheduler must be compatible with the scheduling parameters of all the schedulable resources that it has associated.
- [2] The scheduling policy of the scheduler must be compatible with the ProtectProtocolParameters of all the associated MutualExclusionResources.

10.3.2.16 SecondaryScheduler

The SecondaryScheduler stereotype maps the SecondaryScheduler domain element (section F.4.33, p. 481) denoted in Annex F.

A scheduler of this kind takes its capacity from the set of schedulable resources collected as virtual processing units, and in its turn shares it among its nested served schedulable resources.

Extensions

- None

Generalizations

- Scheduler

Attributes

- None

Associations

- virtualProcessingUnits: SchedulableResource [0..*]
set of virtual processing resources to whose processing capacity the secondary scheduler controls access.

Constraints

- [1] A SecondaryScheduler takes its capacity from the virtualProcessingUnits list of schedulable resources, so it is not possible to have processing resources capacity through the processingUnits list inherited from Scheduler.

10.3.2.17 StorageResource

The StorageResource stereotype maps the StorageResource domain element (section F.4.35) denoted in Annex F.

Extensions

- None

Generalizations

- Resource

Attributes

- elementSize: Integer [0..1] is the size in bits of the basic storage unit.

Associations

- None

Constraints

- None

10.3.2.18 SynchronizationResource

The SynchronizationResource stereotype maps the SynchResource domain element (section F.4.36) denoted in Annex F.

Extensions

- None

Generalizations

- Resource

Attributes

- None

Associations

- None

Constraints

- None

10.3.2.19 TimerResource

The TimerResource stereotype maps the TimerResource domain element (section F.4.37) denoted in Annex F.

Extensions

- None

Generalizations

- TimingResource

Attributes

- duration: NFP_Duration [0..1]
interval after which the timer will make evident the elapsed time.
- isPeriodic: Boolean [0..1]
if true, the timer will indicate the arrival of a new finalization of the programmed interval in a periodic repetitive way. If false, it will do it only one time after it is started.

10.3.2.20 TimingResource

The TimingResource stereotype maps the TimingResource domain element (section F.4.38) denoted in Annex F.

Extensions

- None

Generalizations

- Resource
- ClockType (from MARTE::Time)

Attributes

- None

Associations

- None

Constraints

- None

10.3.3 GRM model library elements description

The description of all the elements in the model library for GRM are in annex D4.

10.4 Examples

The general resource model is planned to be used not only for further extension in the software and hardware platform models, or in the analysis models of this specification, but also as a way to described resources and platform architectures at a very high level, when design choices and analysis techniques to use for the verification are probably still undecided.

The illustration in Figure 10.20 shows a simple example of the platform description for a teleoperated robot using a deployment diagram. This example is further revisited to illustrate the usage of schedulability analysis annotations in section 16.3.3.

The system platform is composed of two processors interconnected through a CAN bus, and a robot arm whose servo control cards are connected by means of a backpanel VME bus.

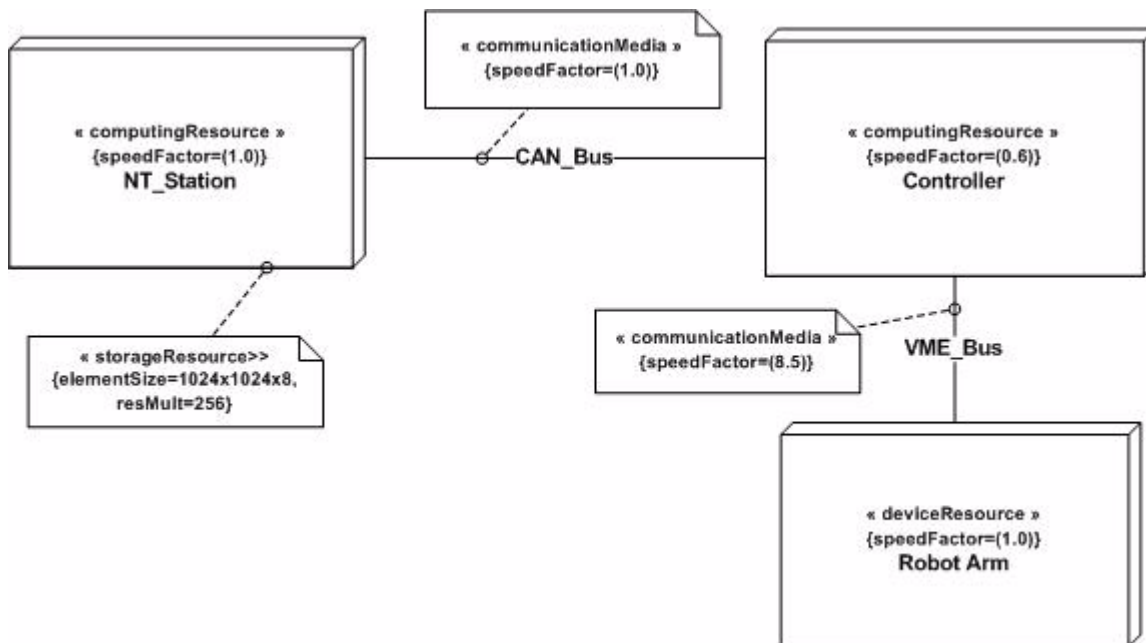

Figure 10.20 - Simple example of usage of the GRM Profile at a high architectural level

The first processor is a teleoperation station (NT_Station); it hosts a GUI application, where the operator commands the robot and where information about the system status is displayed. The second processor (Controller) is an embedded microprocessor that implements the controller of the robot servos and its associated instrumentation. Figure 10.21 shows a possible software architecture for this example.

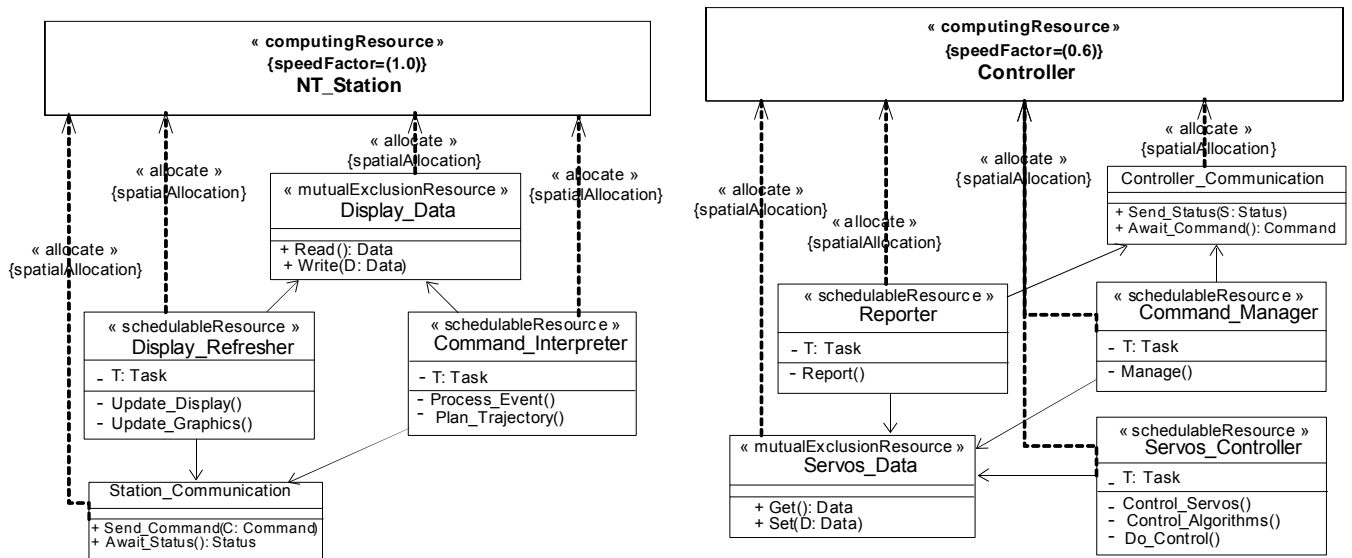

Figure 10.21 - Example of usage of the GRM Profile to annotate initial structural architectural choices

The software of the Controller processor contains three active classes and a passive one which is used by the active classes to communicate. Servo_Controller is a periodic task that is triggered by a ticker timer with a period of 5 ms. The Reporter task periodically acquires, and then notifies about, the status of the sensors. Its period is 100 ms. The Command_Manager task is aperiodic and is activated by the arrival of a command message from the CAN bus.

The software of processor Station has the typical architecture of a GUI application. The Command Interpreter task handles the events that are generated by the operator using the GUI control elements. The Display Refresher task updates the GUI data by interpreting the status messages that it receives through the CAN bus. Display_Data is a protected object that provides the embodied data to the active tasks in a safe way. Both processors have a specific communication software library and a background task for managing the communication protocol.

According to the initial specification the system has at least three end-to-end flows of independent stimuli subject to hard real-time requirements. Each one interferes with the others by sharing the processing resources (Station, Controller and CAN_Bus) and by accessing the protected objects.

One is the basic control algorithm that executes the Control_Servos procedure with a period (and expectably a deadline) of 5 ms. The second is the Report procedure that transfers the sensors and servos status data across the CAN bus, to refresh the display with a period (and deadline) of 100 ms. Finally, the user commands that typically have a sporadic triggering pattern, but whose minimum inter-arrival time between events could be bounded to 1 s.

For illustration purposes Figure 10.22 shows a closer view of the end-to-end flow that makes the periodic reports every tenth of a second by means of a sequence diagram. There, they have been annotated the deadline specification as well as the periodic timing stimuli and the lifelines instances of the resources involved.

Figure 10.22 - Use of the GRM Profile to annotate behavioral specification instances

11 Allocation Modeling (Alloc)

This chapter contains both domain and UML viewpoints for allocation modeling.

11.1 Overview

Allocation of functional application elements onto the available resources (the execution platform) is main concern of real-time embedded system design. This comprises both spatial distribution and temporal scheduling aspects, in order to map various algorithmic operations onto available computing and communication resources and services.

The MARTE profile defines relevant application and execution platform models (chapter 13 and chapter 14). A MARTE allocation is an association between a MARTE application and a MARTE execution platform. Application elements may be any UML element suitable for modeling an application, with structural and behavioral aspects. An execution platform is represented as a set of connected resources, where each resource provides services to support the execution of the application. So resources are basically structural elements, while services are rather behavioral elements.

Application and execution platform models are built separately, before their pairing through the allocation process. Often this requires prior adjustment (inside each model) to abstract/refine its components to allow a direct match. Allocation can be viewed as a "horizontal" association, and abstraction/refinement layering as a "vertical" one, with the abstract version relying on constructs introduced in the more refined model. While different in role, allocation and refinement share a lot of formal aspects, and so both will be described here. This dual function was recognized in SPT, where allocation was called realization, while refinement was used as such.

Application and execution platform elements can be annotated with time information based on logical or physical clocks. Allocation and refinement should provide relations between these timing under the form of constraints between the clocks and their ticks. Other similar non-functional properties definable from the NFPs package (such as space requirement, cost, or power consumption) can also be considered.

Note: we do not use here the UML notion of deployment, but rather a SysML-inspired notion of allocation to emphasize the fact that Execution Platform models should themselves be abstract and not seen as concretization models.

In the simplest case application elements are untimed, without explicit logical clocks attached. Asynchronous parts can also be attached to fully independent virtual clocks. In this simple case the timed allocation provides a physical duration (and maybe other constraints) to the execution of this given application function on this given execution platform service or resource. In the more general case timed allocations provide constraints between the virtual logical clocks on the application side and the more physical technical clocks on the platform side. Clocks on the application side can be important as they allow the user for visualizing a possible scheduling, maybe computed by subsequent tools and respecting the provided scheduling constraints, rather than being provided by the user himself.

Refinement (or its inverse abstraction) should also relate the more abstract clocks to the mode refined. On the application side, abstraction grouping could amount to performing a number of operations in a single instruction (by parallelization, vectorization, or by replacing a task body by a simple call to it). Atomic instants at some level can be subdivided into many micro-steps at a more refined level. On the execution platform side, abstraction can help define new services built as collaborations between resource elements and lower-level services; these services can be generic, or ad-hoc to help represent simply the allocation of application functions using them. Again here the clocks can be subdivided to represent the division of service calls into more atomic services.

Allocation can be specified in different kinds: Structural, behavioral, or hybrid. Structural allocation is an association between a group of structural elements and a group of resources. Behavioral allocation is an association between a set of behavioral elements and a service provided by the execution platform. When clear from context, hybrid allocations can also be allowed (for instance when an implicit service is uniquely defined for a resource). At the finer level of detail, behavioral allocation deals with the mapping of UML actions to resources and services.

The next subsection considers how resources can be grouped to collaborate and provide a given service, possibly with a given scenario. The following subsection describes the principles of the Allocation process (between two previously independent models). The last part deals with NFP annotations.

Grouping process (Abstraction/Refinement)

Allocations concerns groups of elements. Such grouping of resources was already included in the service definition. The intention is as follows: grouping, together with the associations already existing at each side (application or platform), should provide a way to represent a change of atomicity level (abstraction/refinement) inside each model. If a number of application actions (sets of instructions or subprogram) can be realized atomically as a platform service, itself being made of several resources collaborating according to a given scenario, then this scheme allows for linking them by an atomic mapping between the two models. The preliminary process of constructing the entities to be matched is conducted separately, inside each model. This shows a separation of concern between service definition and actual mapping of matching elements.

Groups of services could themselves be viewed as compound services. Keeping the two levels is useful to discriminate between generic services, built on the platform in full isolation, and ad-hoc services, only introduced to cover specific needs of a particular application.

Allocation process

Allocation results in both spatial distribution and temporal scheduling. Spatial distribution is the allocation of computations to processing elements, of data to memories, and of data/control dependencies to communication resources. Scheduling is the temporal/behavioral ordering of the activities (computations, data storage movements or communication) allocated to each resource. Scheduling is represented as a relation between the respective time bases of application and platform elements.

In turn, the potential analysis performed due to allocation mapping may refine "back" the temporal aspects of applications, to reflect the results of constraints (scheduling, resource allocation and sharing) imposed by the execution platform. It may do so according to a possible refinement of the Time model at the application level.

Structural allocation enforces the corresponding behavioral allocation of encapsulated behaviors, so that contained elements "inherits" the allocation of compound structures unless otherwise stated at their level (and then the proper execution platform communication pattern should be feasible). For example, if a Behavior is executed in the context of a particular object, and this object is allocated to a particular ComputingResource C1 for execution, then any `uml::CallBehaviorAction` would by default use the "Call" service provided by C1. However, if the called Behavior belongs to an object to which another ComputingResource is allocated, it uses the "RemoteProcedureCall" service provided by C1 to reach C2 - assuming a communication path exists between C1 and C2.

The allocation model could offer different allocation alternatives for a given application element, so that there is an actual choice on how to map application functions and objects to various parts of the execution platform. The mapping can then be refined and made more precise in several ways by model transformations directed by analysis techniques.

Both spatial and temporal allocations have to be mutually and globally consistent to ensure a correct execution of the application by its deployment on the execution platform. This is in general the topic of analysis techniques that the current MARTE profile aims to offer. But the profile itself only describes the means to describe (total or partial)

allocations, some of which may be provided by users, some computed by advanced analysis techniques in any advanced design methodology associated with the profile. In usage the allocation model can be made to represent relations that are issued to the user from an analysis tool, not just provided by human edition.

Allocations should also comply with, or at least not contradict, the local associations and dependencies internal to both the application and the execution platform. For instance two actions connected by a dependency link should not be mapped to disconnected parts of the platform. Other well-formedness rules for maintaining structural and behavioral consistency are listed below.

Application actions and services both derive from TimedAction, hence have "start" and "end" time value specifications (related to different or to the same logical clock).

When an application action is allocated to an execution platform service, it implies a coincidence relation between all "start" events on the time base supporting the application action, and all "start" events on the time base supporting the execution platform service.

The same coincidence relation is implied for the "end" events on respective time bases. This enforces relations between logical clocks defined by the application, and logical clocks defined by the execution platform.

11.2 Domain View

Figure 11.1 shows a general view of allocation, while Figure 11.2 shows the refinement relations. Both the Allocations and the refinement are annotated with NFP_Constraints as built from the NFP section. Time constraints can also be associated since the metaclass NFP_Constraints is a generalization of the metaclass ClockConstraint defined in the Time Model section (Refer to the section entitled "Time Modeling (Time)" on page 51). Allocations provide links between independent models, while refinement/abstraction works by changing the focus on an underlying similar structure.

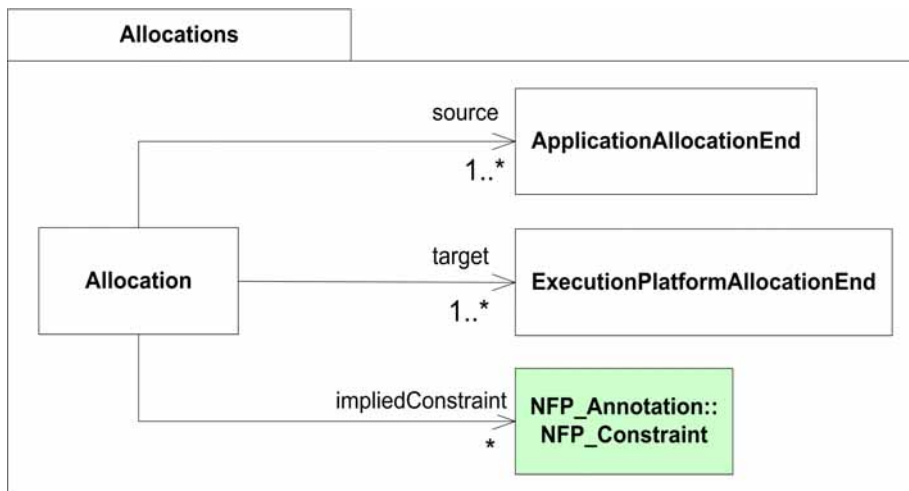

Figure 11.1 - The allocation model

Allocations are used to associate individual application elements to individual execution platform elements. The role of the time constraints in such case is to provide correlations of some sort between the logical/virtual time bases used as activation conditions on the application side, and the more technical/physical time bases used as processor rates in the execution platform side.

Allocation as from SysML can map structural to structural, and behavioral to behavioral or structural elements. The refinement process generally involves the definition of additional constraints to precise links between the general element and the refined ones. For instance, one may want to specify how the time bases relates, how the bandwidth (or power consumption ...) is spread amongst refined elements. The association with some NFPs::NFP_Annotations::NfpConstraint is a provision for defining such links.

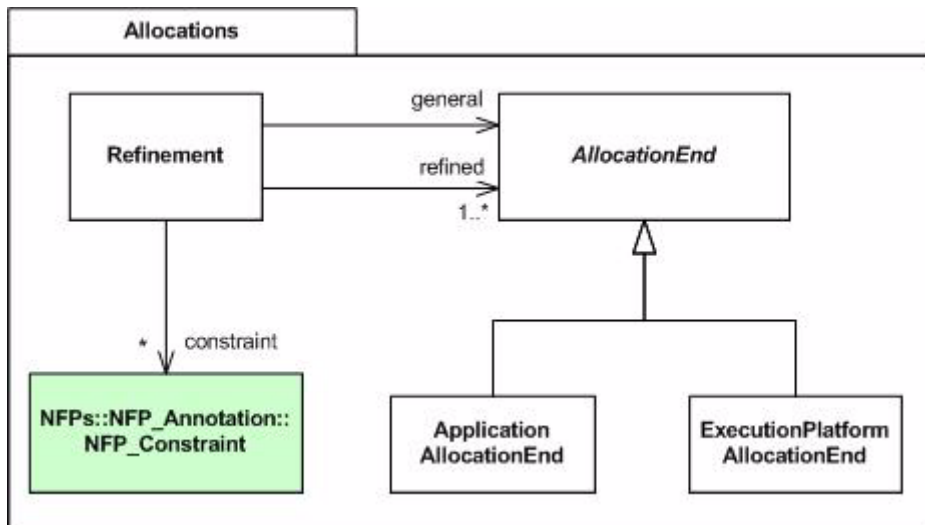

Figure 11.2 - The Refinement model

Refinement can deal with both application models and execution platform model. A single element on the more abstract side can be associated with a number of elements (a group) in the more refined side. In case a group of (structural) resources and (behavioral) services are grouped to form a more abstract behavioral element (a higher-level service), then a collaboration use scenarios or something similar should be introduced to indicate how the cooperation of the more basic entities form the more abstract service is implemented.

For instance on the application side a "task" call can be refined as its body, or arrange of operations can be parallelized (or vectorized) as a single instruction. On the execution platform side a service or transaction can be realized by a sequence of protocol steps.

11.3 UML Representation

The UML view for allocation is strongly inspired from the SysML solution. The SysML solution is satisfactory, but we wanted to emphasize three important points. First, the allocation is a mechanism aiming at defining a mapping from the logical parts (the application model elements) of the model to some more physical parts (the execution platform). Second, there can be several possible allocations and all of them imply a cost that affects the time budget, the power budget or the budget of any other non functional property. Last, there can be at least two reasons to make an allocation: to perform a spatial distribution of artifacts onto resources or resource services, or to schedule algorithmic parts onto available resources.

The allocation package includes all these three points.

11.3.1 Profile Diagrams

The first step is to identify what can be allocated, the logical view-behavior or structure-, and what can serve as a target of an allocation, the physical view-a resource or a service-. The stereotype `Allocated` and its specialization (Figure 11.3 on page 119), `ApplicationAllocationEnd` and `ExecutionPlatformAllocationEnd` are used for this matter.

Figure 11.3 - The stereotype "allocated"

The second step is to identify what is allocated onto what and what are the reasons for such an allocation and what are the constraints implied by this allocation, hence the definition of the stereotype `Allocate`.

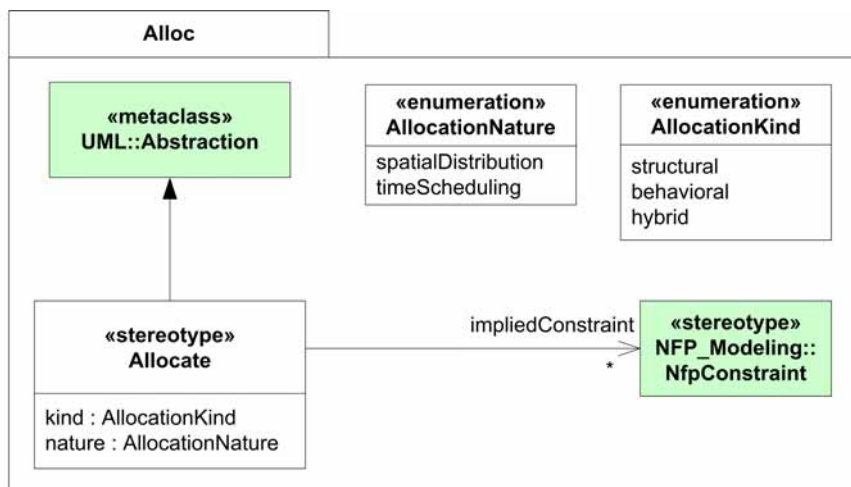

Figure 11.4 - The stereotype "allocate"

As in SysML, a special attention is given to activities since the notation is natural to allocate a set of actions to a structural element (classifier, instance or part). We define the stereotype `AllocateActivityGroup` (Figure 11.5 on page 120), which name is less misleading than `AllocateActivityPartition` that would suggest an actual partition of activity nodes. We intend to represent possible allocations; we anticipate several cases where activity nodes will be shared by

several allocate activity groups. In this case, that means the shared activity nodes can be allocated either to one activity partition (an instance of the classifier, the instance itself or the instance playing the part represented by the activity partition) or to the other. The isUnique property explicitly prevents an activity node from being allocated to several groups. This does not mean the node cannot be shared by several groups, it only means that once we have made the final decision of the allocation, the node is actually allocated to only one group.

Figure 11.5 - The stereotype "AllocateActivityGroup"

For the purpose of specifying refinement, the abstraction mechanism offered by UML and the UML keyword refine are enough. Defining abstractions is useful in bottom-up approaches while making refinement is useful in top-down approach.

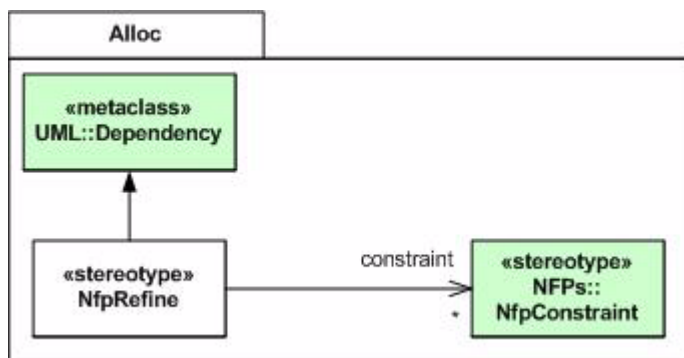

Figure 11.6 - The stereotype "NfpRefine"

Concerning the refinement we also think it is important to emphasize the fact that the refinement process implies some additional constraints. It could be ClockConstraints to relate clocks at the different abstraction level or any other NfpConstraint.

11.3.2 Profile elements description

11.3.2.1 Allocate (from Alloc)

The Allocate stereotype maps the Allocation domain element (section F.5.1 on page 554) denoted in Annex F.

Allocate is a dependency based on UML::Abstraction. It is a mechanism for associating elements from a logical context, application model elements, to named elements described in a more physical context, execution platform model elements.

The dependency Allocate can be used either to specify one possible allocation, in which case, a space exploration tool may determine what the best allocations are, or to specify an actual allocation in the system. The context in which the allocate dependency is used should be sufficient to know in which case we are.

As a named element, a dependency can be constrained by any kind of UML::Constraint including NfpConstraint. The purpose of the impliedConstraint association is to explicitly identify what are the constraints that only apply if or when the allocation is performed. When it is not the case, the kind of the constraints may help in determining whether the allocation is required, offered, etc.

When the nature is TimeScheduling, the allocate dependency represents a set of timed application model elements (the supplier)-that may be grouped using the stereotype RefineClock-scheduled on to timed execution platform model elements. The relation amongst the clocks of the suppliers and the clients-the scheduling-is given by a set of clock constraints.

Extensions

- Abstraction (from Dependencies).

Associations

- impliedConstraint: NFPs::NfpConstraint [*]
The set of constraints implied by the allocation. Allocating an application model element on a resource has a cost. This cost is described using a set of non functional property constraints.

Attributes

- kind: AllocationKind [1]
This differentiates the kind of allocations, whether both allocated elements on each side are structural, behavioral or whether this is an hybrid allocation.
- nature: AllocationNature [1]
This identifies the purpose of the allocation, whether the allocation is equivalent to a spatial distribution, where several application model elements are distributed to different resources or whether timed elements are scheduled according to a given scheduler.

Constraints

- [1] When the kind is structural, suppliers and clients must all be structural elements: classes, instance specifications or packages. When the kind is behavioral, suppliers must be UML::Behavior or UML::Action and the clients must be behavioral elements, a UML::BehavioralFeature for example. When the kind is hybrid, suppliers must be behavioral elements while the clients must be structural elements.
- [2] When the nature is TimeScheduling, supplier and the clients must be Time::TimedElement and the NFPs::NfpConstraint shall include Time::ClockConstraint.

Notation

The "allocate" relationship is a dashed line with an open arrow head. The arrow points in the direction of the allocation. In other words, the directed line points "from" the elements being allocated "to" the elements that are the targets of the allocation

11.3.2.2 AllocateActivityGroup (from Alloc)

AllocateActivityGroup is used to depict an allocation relationship on an Activity. It is an extension of the metaclass UML::ActivityPartition.

AllocateActivityGroup is a standard UML::ActivityPartition, with modified constraints such that any actions within the partition must result in an "allocate" dependency between the activity used by the action, and the element that the partition represents.

Since we also intend to represent possible allocations, we anticipate several cases where activity nodes will be shared by several allocate activity groups (Figure 11.9 on page 127). In this case, that means the shared activity nodes can be allocated either to one activity partition (an instance of the classifier, the instance itself or the instance playing the part represented by the activity partition) or to the other. The isUnique property explicitly prevents an activity node from being allocated to several groups. This does not mean the node cannot be shared by several groups, it only means that once we have made the final decision of the allocation, the node is actually allocated to only one group.

Extensions

- ActivityPartition (from IntermediateActivities).

Attributes

- isUnique: Boolean=false
This specifies whether or not the actions contained in the partition can actually be allocated to several partitions (the default) or can only be allocated to only one.

Constraints

- [1] All Actions appearing in an AllocateActivityGroup will be the /suppliers (from) end of a single Allocate dependency. The element represented by the AllocateActivityGroup will be the /client (to) end of the same Allocate dependency. This allows for defining non functional property constraints applying to all contained actions.

Notation

For brevity, the keyword used on an AllocateActivityGroup is "allocate", rather than the stereotype name ("allocateActivityGroup").

11.3.2.3 Allocated (from Alloc)

The Allocated stereotype maps the AllocationEnd domain element (section F.5.2 on page 555) denoted in Annex F.

The stereotype Allocated applies to any named element that has at least one allocation relationship with another named element. Allocated named elements may be designated by either the /from or /to end of an "allocate" dependency.

The stereotype Allocated provides a mechanism for a particular model element to conveniently retain and display the element at the opposite end of any "allocate" dependency. With this stereotype you can allocate anything on anything. To make it clear you want to allocate something logical, from the application model, to something more physical (a resource or a resource service), more specific stereotypes-ApplicationAllocationEnd and ExecutionPlatformAllocationEnd-should be used instead.

The stereotype Allocated is kept as a concrete stereotype to keep some compatibility with the SysML stereotype that has the same name, but more specific stereotypes-ApplicationAllocationEnd and ExecutionPlatformAllocationEnd-should be used instead when possible.

Extensions

- NamedElement (from Dependencies)

Associations

- None.

Attributes

- /allocatedTo: Allocated [*] named elements that are suppliers of an "allocate" whose client is extended by this stereotype. This property is the union of all suppliers to which this instance is the client. This association is derived from any "allocate" dependency
- /allocatedFrom: Allocated [*] named elements that are clients of an "allocate" whose supplier is extended by this stereotype. The allocatedFrom elements are not necessarily derived from the same "allocate" dependency. A given element can be the supplier of several application model elements, each of which is allocated using a separate "allocate" dependency. The association is derived from any "allocate" dependency.
- kind: AllocationEndKind [1] = undef specifies the kind of allocation end.

11.3.2.4 AllocationEndKind (from Alloc)

AllocationEndKind is an enumeration type that differentiates the application allocation end from the execution platform allocation end.

Literals

- undef should be used when no differentiation is to be made on the nature of the allocation end. It could be either an application allocation end or an execution allocation end or something else (as in SysML, where no distinction is made).
- application identifies an allocation end as being on the application side of the allocation. This allocation end must be the source (the client) of an allocate dependency.
- executionPlatform identifies an allocation end as being on the execution platform side of the allocation. This allocation end must be the target (the supplier) of an allocate dependency.
- both identifies an allocation end as being both on the application and the execution platform side of the allocation. This allocation must be the source (the client) of an allocate dependency and the target (the supplier) of an (another) allocate dependency.

11.3.2.5 AllocationNature (from Alloc)

AllocationNature is an enumeration type that defines literals used to specify the purpose of the allocation.

Literals

- spatialDistribution it indicates that the suppliers are distributed on the clients. Spatial distribution is the allocation of computations to processing elements, of data to memories, and of data/control dependencies to communication resources.

- `timeScheduling` it indicates that the allocation consists in a temporal/behavioural ordering of the suppliers, the order being given by the clients. Scheduling is the temporal/behavioral ordering of the activities (computations, data storage movements or communication) allocated to each resource.

11.3.2.6 AllocationKind (from Alloc)

AllocationKind is an enumeration type that defines literals used to specify the kind of named elements that are used as clients and suppliers.

Literals

- `structural` indicates that the suppliers and the clients are all structural named elements.
- `behavioral` indicates that the suppliers and the clients are all behavioral named elements.
- `hybrid` indicates that the suppliers and the clients are not of the same kind.

11.3.2.7 NfpRefine (from Alloc)

The stereotype NfpRefine maps the domain element Refinement (section F.5.5 on page 556) denoted in Annex F.

NfpRefine is a dependency based on UML::Dependency. It is a mechanism for associating one abstract model element to refined model elements. It is a provision for grouping elements. The refinement process implies some additional constraints between the abstract element and the refined elements.

When several application model elements are to be collectively allocated to execution platform elements they should first be grouped using the dependency NfpRefine. Some NfpConstraints, like for instance ClockConstraint, should be associated with this dependency to specify relations between the general element and the refined ones.

Extensions

- Dependency (from Dependencies).

Associations

- `constraints: NFPs::NfpConstraint [*]` The set of constraints implied by the refinement.

Constraints

[1] A singledependency NfpRefine shall have only one client (from), but may have one or many suppliers (to).

context NfpRefine

inv: base_Dependency.from->size()=1 and base_Dependency.to->size()>=1

[2] The client and the suppliers must be Time::TimedElement.

Notation

The relationship NfpRefine is a dashed line with an open arrow head. The arrow points in the direction of the refinement. In other words, the directed line points "from" the element being refined "to" the elements that are the refined elements.

11.4 Examples

11.4.1 Unix process

Figure 11.7 shows an example of allocations with three layers. The first layer describes the application point of the view, the second layer represents the operating system internals and the last layer shows the hardware parts. We use structured classifiers to represent both hardware and software resources.

The example models the design of a given operating system family, not a particular implementation. It represents a typical Unix operating system. A VxWorks model or an embedded Unix model would show a different partition of memory (e.g., no virtual memory). An Arinc653 OS model would show the explicit "partitions" as both space and time partitioning of hardware resources.

A refinement down to Posix threads would show further partitioning of the CPU resources without further partitioning of Memory.

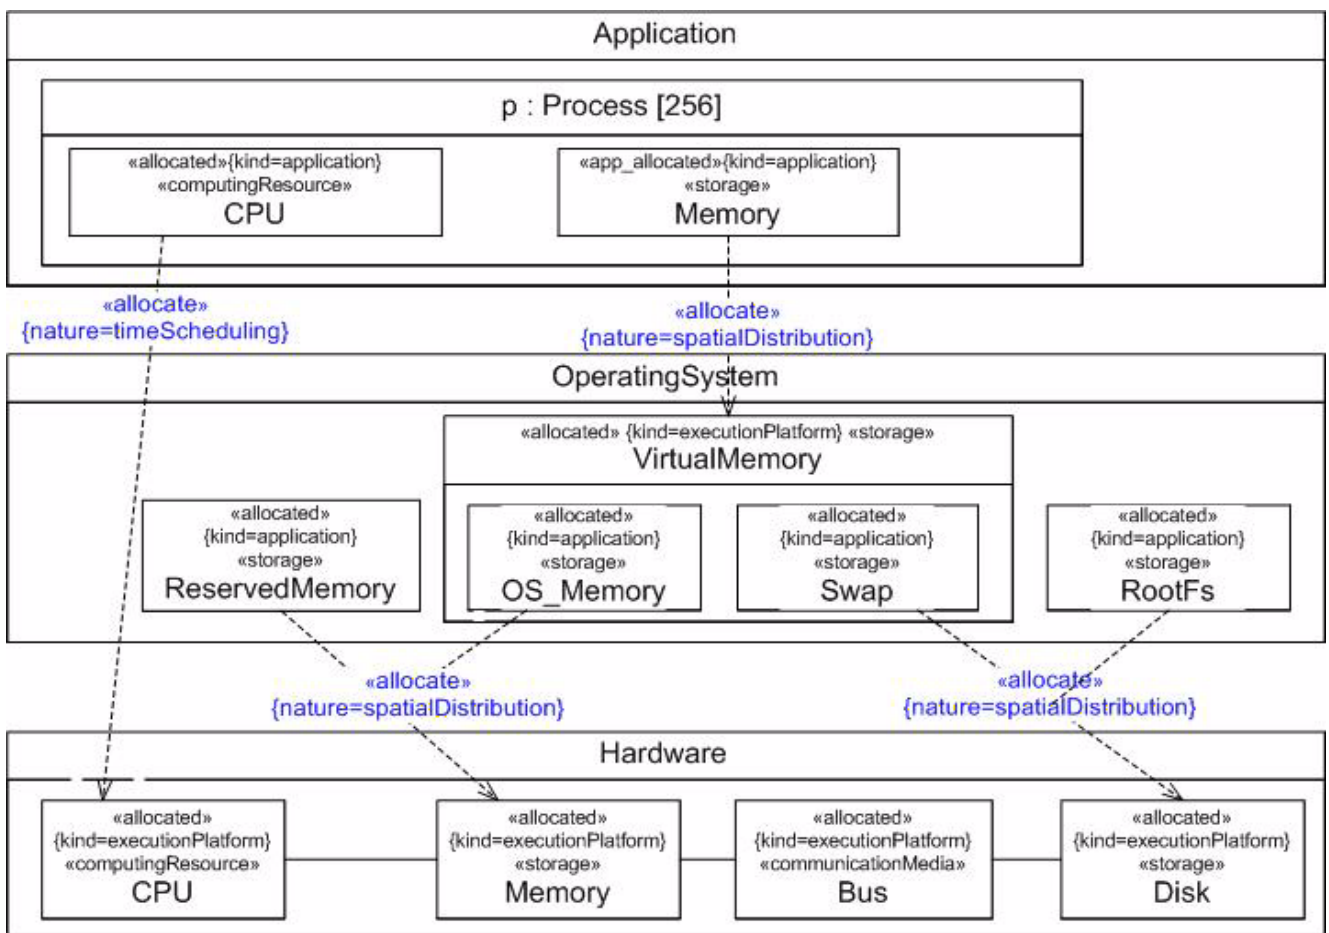

Figure 11.7 - Allocation of Unix processes

The diagram shows several resources such as computing resources, communication media and storage (using stereotypes defined in GRM), and how these resources can be grouped using a structured classifier and how they can be allocated to more physical resources.

The lower layer in the diagram represents the hardware elements.

The top layer is the view from the application: a (Unix, in this example) process is a group involving a time shared access to a computing resource, and a “spatial” partition in the virtual memory.

The intermediate layer is the implementation internals. The VirtualMemory is the high-level view as seen from the application process. Physically, this virtual memory relies on two types of physical storage (the actual physical memory and a hard disk).

This diagram is for illustration purpose. Often hard real-time application do not need to model the virtual memory and swap space, since a prior analysis based on a simpler model would have verified that the worst case memory requirement does not exceed available RAM memory.

11.4.2 System on Chip

To illustrate the use of the stereotype “clockRefine” we take the example of a system on chip (Figure 11.8 on page 126). We first decide that we need to have a digital signal processor (e.g., the OAK+) to compute floating point operations and a Risc processor (e.g., an ARM 7) to control the whole application. The two processors are meant to communicate but we do not elaborate on the communication itself at this point (cf. Figure 11.8 on page 126, upper part).

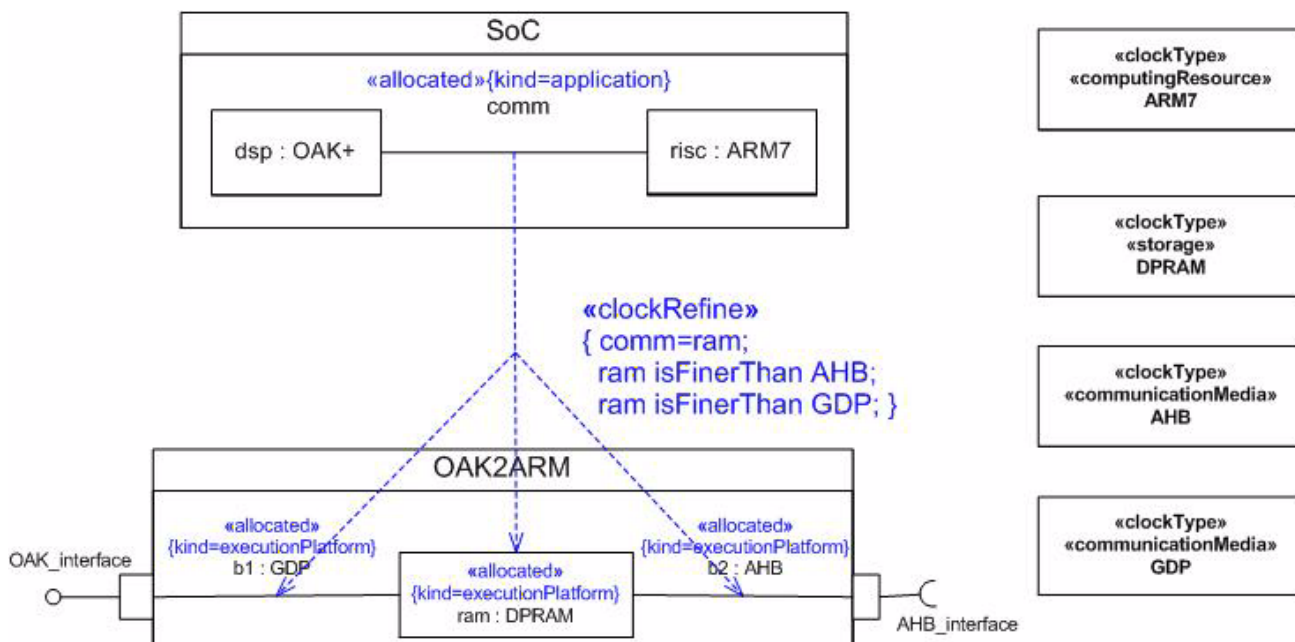

Figure 11.8 - Communication refinement

We then decide to refine the communication (cf. Figure 11.8 on page 126, lower part). We use a double port Ram for the communication. The bus coming from the OAK+ is the GDP bus and the bus coming from the ARM7 conforms to the AMBA High-performance Bus specification. The "clockRefine" dependency specifies that these two connectors (GDP, AHB) and this part (ram : DPRAM) are refinements of the connector comm. Each named element involved in these structured classifiers are typed by a class stereotyped "clockType" (cf. Figure 11.8 on page 126, right part), which means there is no a priori assumption on relative rates of each part of this diagram. Additionally, the clock constraints associated with the dependency constrain these rates by stating that:

- The clock of the instance that is to be used to conform to the role ram, is the same than the macroscopic clock perceived for the global communication between the OAK+ and the ARM7;
- The clock of this instance is finer than the clock of the two busses (b1 : GDP and b2 : AHB). This is probably an over specification and the Time Model chapter (Refer to the section entitled “Time Modeling (Time)” on page 51) offers several clock relations that allows for defining constraints more accurate.

Note that using a single dependency rather than three separate ones gives a stronger specification because the dependency identifies a common context that gathers all four constrained elements.

11.4.3 Allocate activity group

To illustrate the use of the stereotype `AllocateActivityGroup` with take the example of a system described using an activity (Figure 11.9 on page 127). The activity groups (P1 and P2) represent processors that are the potential clients for the actions of the activity. Because of the nature of the processor (digital signal processor or general purpose processor) and because of the physical localization of sensors (used by actions `inpC`, `outW` and `outZ`) some processing elements cannot be executed by one processor or another. For instance, the operation `oper1` requires a hardware coprocessor not included on processor P2. However, the operation `oper2` can be allocated to both processors even though the cost of the allocation (not represented here) could be different. An analysis tool could use this information to choose the best allocation regarding, for instance, to a time budget.

Had we wanted to represent the allocation cost, we would have used the non functional property constraints defined in NFP chapter. For clarity, we can either draw explicitly dependencies or draw a separate table that would present the cost of each allocation.

Figure 11.9 - Actions shared between two allocate activity groups

The table below illustrates how to complete the allocation information of Figure 12.9 to represent the cost:

	P1	P2
inpC	4 ms	6 ms
oper1	10 ms	
oper2	10 ms	8 ms
outW	4 ms	
outZ		6 ms

We use the standard notation for NFP Constraints, either the simplify version or the full tuple notation. Several constraints can be put in the same cell or a different table can be done for each different constraint. Any kind of NFP constraints can be specified (time, power consumption ...).

Part II - MARTE Design Model

This Part contains the following chapters.

- 12 - Generic Component Model (GCM)
- 13 - High-Level Application Modeling (HLAM)
- 14 - Detailed Resource Modeling (DRM)

12 Generic Component Model (GCM)

12.1 Overview

The MARTE GeneralComponentModel presents additional concepts (w.r.t usual component paradigms) that have been identified as necessary to address the modeling of artifacts in the context of real-time and embedded systems component based approaches. Figure 12.1 shows the dependencies of this package.

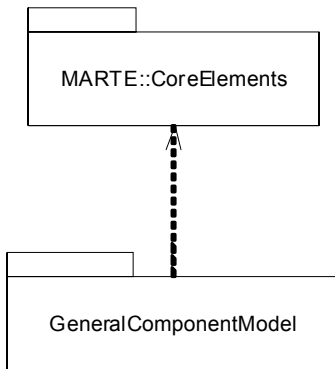

Figure 12.1 - Dependencies of the GeneralComponentModel package

Additionally, the MARTE general component model defines shortcut notations that help in simplifying the modeling and are useful in the application of component base strategies in the real-time and embedded systems domains.

12.2 Domain View

12.2.1 The GeneralComponentModel Package

The general component model introduced in this specification proposes mainly refinements to the UML structured classes. This model provides a common denominator among various component models, which in principle do not target exclusively the real-time and embedded domain. The purpose is to provide in MARTE a model as general as possible, that is not tied to specific execution semantics, on which real-time characteristics can be applied later on. The MARTE general component model relies mainly on UML structured classes, on top of which a support SysML blocks has been added. Providing a support for Lightweight-CCM, AADL and EAST-ADL2 have also influenced the definition of some refinements of the MARTE General Component Model.

Figure 12.2 - The bulk of the MARTE GeneralComponentModel package

A StructuredComponent defines a self-contained entity of a system, which may encapsulate structured data and behavior. A MARTE structured component specializes the BehavedClassifier classifier. It owns properties that can be used as AssemblyParts within an internal component description, attributes, or member ends of an association. When used as an assembly part, a property is indicated in the parts reference. As mentioned in the CoreElements package, Property is similar to the corresponding UML definition, i.e. it has a multiplicity in terms of upper and lower bounds, an aggregation kind and a type (as a Classifier). InteractionPorts are a special kind of properties owned by a structured component. An interaction port defines an explicit interaction point through which components may be connected (linked) through an AssemblyConnector. One may also directly connect structured component with no port. In any case, related ports need to be compatible regarding their provided/required services or flow specifications and directions.

Underlying execution semantics (i.e., what happens when the component is in operation, when it receives external stimuli) are left undefined at this stage so that multiple component models may match the definition above.

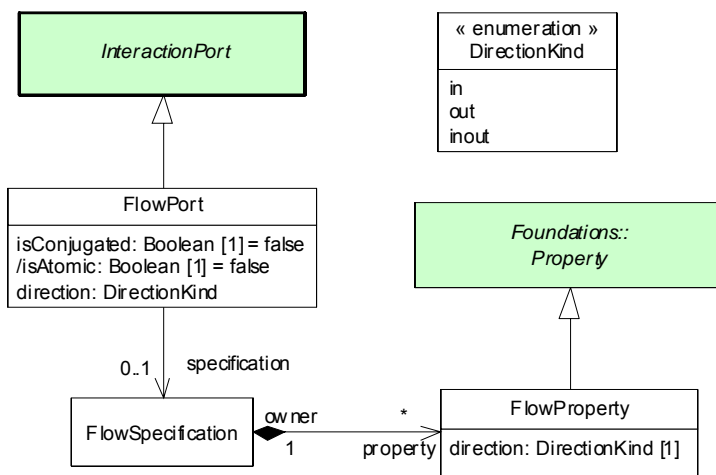

Figure 12.3 - Flow ports of the GeneralComponentModel package

One of the main reasons to have refined the UML component model within this specification is to support both message- and flow- oriented communication schemas.

FlowPorts have been introduced to enable flow-oriented communication paradigm between components. A flow port enables to specify the nature of flow that it may relay. A flow port may handle incoming (in), outgoing (out) or bidirectional (inout) flows. If a flow port is atomic, the "type" association role, inherited from Property, is used to specify the nature of the flow and its "direction" attribute is used to specify the direction. If the port is not atomic, the "specification" association role is used to specify the nature of the flow using a FlowSpecification. The flow direction has to be fixed for each FlowProperty owned by the FlowSpecification then. An atomic flow port typed by a Signal, specifying an incoming flow direction, maps to a Reception of the signal. An atomic flow port typed by a signal, specifying an outgoing flow direction, declares the ability for the port to relay the signal over connectors. Flow properties support incoming and outgoing signals the same way.

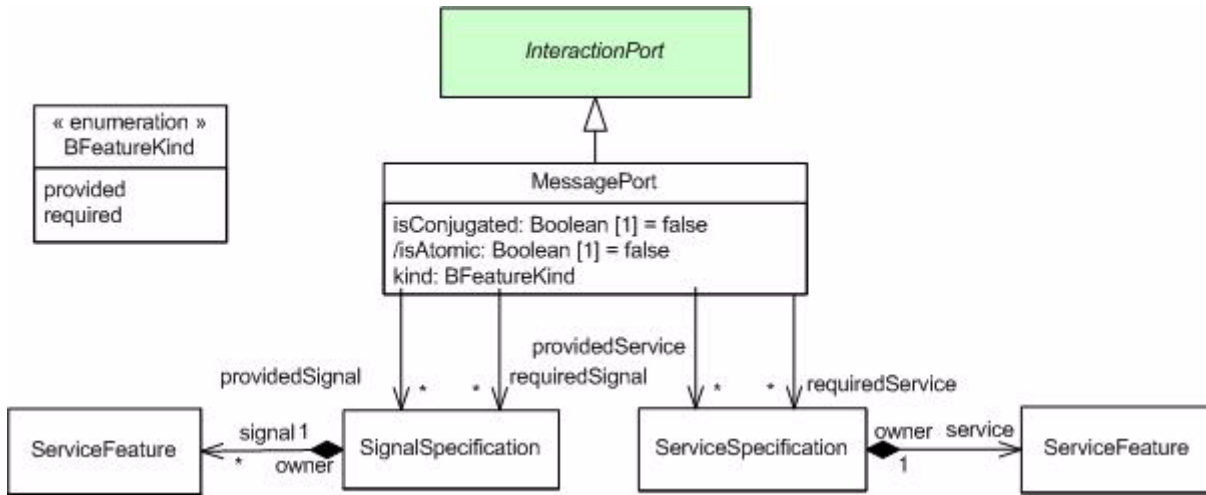

Figure 12.4 - Message ports of the GeneralComponentModel package

Message ports support a request/reply communication paradigm. In one hand, they may provide or/and require services (**ServiceSpecification**) and in other hand they may also publish or/and consume signals defined in **SignalSpecifications**. **SignalSpecifications** have a set of **SignalFeatures** defining published (required) and consumed (provided) signals, which are specified by the direction attribute. Particularly, atomic message ports (attribute `isAtomic` to true) cannot require and provide services. If the kind value of an atomic message ports is "provided" (resp. "required"), it "consumes" (resp. "produces") one and only one signal. **ServiceSpecifications** are defined by a set of **ServiceFeatures**.

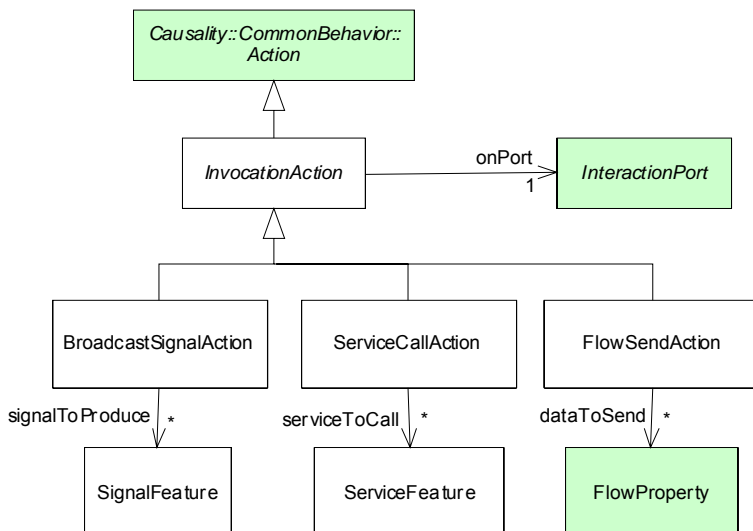

Figure 12.5 - Kinds of InvocationAction in the GeneralComponentModel package

In order to deal with the specific case of communication actions for components, the Action concepts introduced in the CoreBehaviorModel package has been specialized into the InvocationAction classifier. This action models a communication action between components via its exposed ports and it refined in three kinds of invocation actions: BroadcastSignalAction enables a component a send a signal on a port, ServiceCallAction is used to call a service provided by a component though one its ports, and SendFlowAction enables a component to send a data flow via ports.

12.3 UML Representation

The concepts presented in the domain view of the General Component Model are here mapped to concrete UML stereotypes for implementing in practice the corresponding extensions to UML. The stereotypes proposed extend those elements of UML that better catch the semantics, expressiveness, and notation of the concepts introduced, but there is not formal relationship between these UML meta-classes and the concepts used in the domain view for its semantic definition.

12.3.1 Profile Diagrams

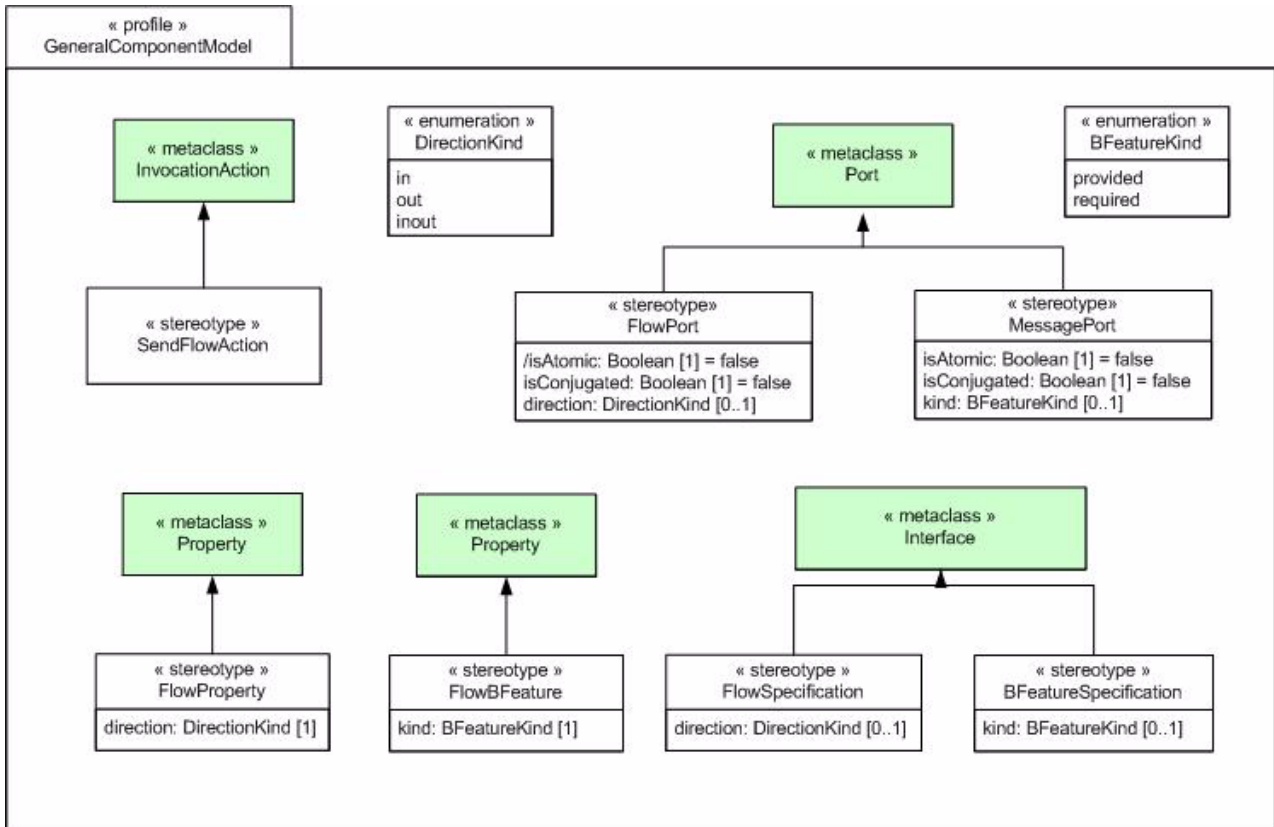

Figure 12.6 - UML2 profile of the MARTE GeneralComponentModel

12.3.2 Profile Elements Description

This section describes in details each elements introduced in the profile diagram described previously. The following list is sorted in alphabetical order.

12.3.2.1 BFeatureKind

It is used with atomic flow (or message) ports to specify the direction of a flow element or a signal that types the port. It can be also used with non-atomic flow (or message) ports to specify the direction of a flow specification (or signal specification), or the direction of its owned properties.

Literals

- required used to model that an operation or a (signal) reception is required.
- provided used to model that an operation or a (signal) reception is provided.

12.3.2.2 BFeatureSpecification

The BFeatureSpecification stereotype maps to both SignalSpecification and ServiceSpecification domain elements as described in Section F.6.19 on page 564 and Section F.6.16 on page 563.

A BFeatureSpecification provides a way to define specialized interface that allows for defining its nature in terms of either its ability to receive and send UML signals, or of its provided and required operations.

Extensions

- Interface.

Generalizations

- None.

Attributes

- kind: BFeatureKind [0..1]
nature of the BFeatureSpecification. If present, all the BehavioralFeature contained in the interface will of the specified kind.

Associations

- None

Constraints

[1] A flow specification owns only properties, it cannot own operation or reception.

Notation

When applying the stereotype using its iconographical or shape forms, following icons are proposed:

- for BFeatureSpecification with kind = required, when all the features contained in the interface are signal receptions;
- ▀ for BFeatureSpecification with kind = provided, when all the features contained in the interface are signal receptions;
- ⤵ for BFeatureSpecification with kind = required, when all the features contained in the interface are operations;
- for BFeatureSpecification with kind = provided, when all the features contained in the interface are operations.

Figure 12.17 describes an example using different graphical forms applying UML stereotypes.

Figure 12.7 - Examples of BFeatureSpecification

12.3.2.3 DirectionKind

This enumeration maps the DirectionKind domain concept defined in Section F.6.5 on page 558 of Annex F.

It is used with atomic flow (or message) ports to specify the direction of a flow element or a signal that types the port. It can be also used with non-atomic flow (or message) ports to specify the direction of a flow specification (or signal specification), or the direction of its owned properties.

Literals

- **in** The direction of the information flow is from outside to inside of the owning entity. When related to a signal, it is usual to say that the signal is consumed.
- **out** The direction of the information flow is from inside to outside of the owning entity. When related to a signal, it is usual to say that the signal is produced or published.
- **inout** The information flow is bidirectional.

12.3.2.4 FlowBFeature

This FlowBFeature stereotype maps both SignalFeature and ServiceFeature domain elements as described in Section F.6.17 on page 563 and Section F.6.14 on page 562.

A FlowBFeature specifies the nature of a BehavioralFeature owned by interfaces stereotyped as "BFeatureSpecification". If kind is required it is expected to be a required operation or signal reception while if kind is provided, it is expected to be a provided operation or signal reception.

Extensions

- BehavioralFeature (from UML::Kernel).

Generalizations

- None.

Attributes

- **kind: BFeatureKind [1]** nature of the FlowBFeature.

Associations

- None.

Constraints

- None.

12.3.2.5 FlowPort

This stereotype maps the concept of FlowPort defined in Annex F. A FlowPort may relay incoming, outgoing or bidirectional flows. The nature of the flow can be specified by a property type in the case of an atomic flow port. A flow can be also specified in terms of flow specifications and flow properties, in the case of a non-atomic flow port.

Extensions

- Port (from UML::Ports)

Generalizations

- None.

Attributes

- isAtomic: Boolean [1] = false
If true, the port is said to be an atomic port, otherwise it is considered as a non-atomic port. An atomic port is typed by a Classifier, Signal, a DataType or a PrimitiveType.
- isConjugated: Boolean [1] = false
If true, the port is said to be a conjugated port. In this case, all the directions of the flow properties (FlowProperty) specified by a FlowSpecification that types a port are relayed in the opposite direction (e.g., an incoming flow property is treated as an outgoing flow property by the FlowPort). By default, the value is false. This attribute applies only to non-atomic ports.
- direction: DirectionKind [0..1]
It specifies the direction of the port when the port is atomic. In other case, this property is not applicable.

Associations

- None

Constraints

[1] A conjugated port may be involved in only bidirectional connector, i.e., connector with exactly two connector ends.

[2] If a port is non-atomic, it cannot specify a direction.

$\text{self.isAtomic} = \text{false} \text{ implies } \text{self.direction} \rightarrow \text{size}() = 0$

[3] A conjugated port cannot be an atomic port.

$\text{self.isConjugated} = \text{true} \text{ implies } \text{self.isAtomic} = \text{false}$

[4] The type of a non-atomic flow port has to be a flow specification (i.e. an interface stereotyped with "flowSpecification").

Notation

When a flow port is atomic, the following graphical notation may be used:  for incoming atomic flow ports;  for outgoing atomic flow ports;  for bidirectional atomic flow ports. Figure 11.8 shows an example of a Speedometer class owning a port called outSpeed. This port is an outgoing atomic flow port typed as Integer. That means that instances of this Speedometer class can send outSpeed Integer data to other external elements connected to this port (Note that Figure 11.9.i used the stereotype notation mixing both text and icon forms, whereas Figure 11.9.ii uses only the icon form).

Figure 12.8 - Example of atomic flow port

When a flow port is non-atomic, the following icon may be used for the stereotype (Figure 11.9): .

Figure 12.9 - Example of non-atomic flow port

12.3.2.6 FlowProperty

This stereotype maps the *FlowProperty* domain concept defined in Section F.6.8 on page 560. A FlowProperty defines the type and the direction of a single flow element carried through flow ports. It may relate to a Classifier, a Signal, a PrimitiveType or a DataType. A flow property is used as part of a flow specification to characterize the type of a non-atomic flow port.

Extensions

- Property

Generalizations

- None

Attributes

- direction: DirectionKind [1] direction of the flow property.

Associations

- None

Constraints

- None

Notation

When applying the stereotype using its iconographical form, following icons are proposed:  for incoming flow properties;  for outgoing flow properties;  for bidirectional flow properties. Figure 11.10 describes an example using both textual and iconographical forms of the stereotype.

Figure 12.10 - Example of flow properties

12.3.2.7 SendFlowAction

This stereotype maps the SendFlowAction domain concept defined in Section F.6.6 on page 558 of Annex F. A FlowSendAction is used to send a flow to other connected components. In that case, connected component ports indicate that they accept this type of flow in input.

Extensions

- InvocationAction (from UML2::CompositeStructure).

Generalizations

- None

Attributes

- None

Associations

- None

Constraints

- None

Notation

Within activity diagrams, a FlowSendAction is notated with a convex pentagon, where:

```

<flow-send-action> ::= 'send('(<flow-property>'='
<value-specification>)+') via '<port-name>

<value-specification> defined in VSL (Annex B, p.353).

<port-name> ::= <string-literal>

<flow-property> ::= <string-literal>

<string-literal> defined in VSL (Annex B, p.353).
```

Figure 11.11 depicts an example of a flow send action consisting in sending the integer value 4 via its port called outSpeed.

Figure 12.11 - Example of FlowSendAction within an activity diagram

12.3.2.8 FlowSpecification

This stereotype has been defined to specialize interfaces used to type flow port (domain concept introduced Section F.6.7 on page 558) in order to enable the description of the different data a flow port may relay.

Extensions

- Interface.

Generalizations

- None.

Attributes

- direction: DirectionKind [0..1]
specifies if the interfaces is an in, out or inout data flow interface. That means respectively that the interface owns only in, out or inout FlowProperty. The services of a ServiceSpecification are its owned operations.

Associations

- None

Constraints

- [1] If the direction of flow specification is "in", all its owned flow property must be conformed to this direction (i.e., only in flow properties).
- [2] If the direction of flow specification is "out", all its owned flow property must be conformed to this direction (i.e., only out flow properties).

Notation

When applying the stereotype using its iconographical or shape forms, following icons are proposed:  for in flow specifications;  for out flow specifications;  for inout flow specifications. Figure 11.12 describes an example using different graphical forms applying UML stereotypes.

Figure 11.12 describes an example using different graphical forms applying UML stereotypes.

Figure 12.12 - Example of flow specification

12.3.2.9 MessagePort

This stereotype maps the MessagePort domain concept defined in Section F.6.12 on page 561.

Extensions

- Port (from UML::Ports)

Generalizations

- None

Attributes

- /isAtomic: Boolean [1] = false
if true, the port is said to be an atomic port, otherwise it is considered as a non-atomic port.
- isConjugated: Boolean [1] = false
if true, the port is said to be a conjugated port. In this case, all the directions of the flow properties (FlowProperty) specified by a FlowSpecification that types a non-atomic port are relayed in the opposite direction (e.g., an incoming flow property is treated as an outgoing flow property by the FlowPort). By default, the value is false and this attribute applies only to non-atomic ports.
- kind: BFeatureKind [0..1]
specifies the kind of the port when the port is atomic. In other case, this property is not applicable.

Associations

- None

Constraints

[1] A conjugated port may be involved in only bidirectional connector, i.e., connector with exactly two connector ends.

[2] If a port is non-atomic, it cannot specify a kind.

self.isAtomic = false implies self.kind->size() = 0

[3] A conjugated port cannot be an atomic port.

self.isConjugated = true implies self.isAtomic = false

[4] If a message port is atomic then its type has to be a Signal.

Notation

When a message port is atomic, the following graphical notation may be used:  for one port consuming signal occurrences according to its type (i.e., kind set to provided);  for one port producing signal occurrences according to its type (i.e., kind set to required).

Figure 12.13 denotes an example of UML component owning a message port as defined in this specification. The CarSpeedRegulator component has an atomic message port typed by the Start Signal. That means its potential instances will consume Start signal occurrences.

Figure 12.13 - Example of atomic message port

When a message port is non-atomic, the following icon may be used for the stereotype (Example in Figure 12.4 on page 134): .

Figure 12.14 - Example of non-atomic message port

12.4 Examples

12.4.1 Automotive Example

The example shown in Figure 12.5 denotes the interface description for the example of component model depicted previously. The package SpeedRegulatorInterfaces consists of three interface definitions and one signal declaration. The RegInterface is a UML2 interface stereotyped with "bFeatureSpecification" because it specifies that the Start signal may be consumed (this latter has been previously declared within the package SignalDeclarations) and the controlEngine service is required. The ECInterface interface is also stereotyped as bFeatureSpecification (in this case, the graphical representation of this interface shown at top-right side of Figure 12.5 only displays its associated iconographic representation "<>"). This interface defines the controlEngine required service (denoted here by an icon representing an half circle placed before the operation name). Finally, the SpeedInterface interface is a "signalSpecification" interface that declares a produced signal, Start (in this case, we only used the textual form of the stereotype). These interfaces illustrate the use of stereotypes defined in the general component model of MARTE. The three possibilities offered by UML to represent the stereotypes have been used here: textual and iconographic form (e.g., RegInterface), only iconographic form (e.g., ECInterface) and only textual form (e.g., SpeedInterface).

Figure 12.15 - Interfaces definition for a speed regulator example

The example shown in Figure 12.6 denotes a *CarSpeedRegulator* composite class: its exposed ports and its internal parts. This class has two ports stereotyped with «messagePort»: *regOn* and *engineCmd*. The former port is an atomic port and its kind is set to required (Note that the attribute values of the applied stereotype are shown in the comment symbol attached to the stereotyped port). The port is typed with the *Start* signal (see previous definition of this signal in the package *SignalDeclarations* in Figure 12.15). *CarSpeedRegulator* exposes then to its environment a port through which it can consume *Start* signal occurrences. The second port exposed by *CarSpeedRegulator* is called *engineCmd*. It is a port stereotyped by «messagePort». Note that the attribute values of the applied stereotype are not shown in this case, because we apply here the default values, i.e., *isAtomic* = false and *isConjugated* = false. The direction property of the stereotype does not apply in this case because the type of the port is an interface stereotyped with "bFeatureSpecification" (this latter, *ECInterface*, defines a required service as denoted in Figure 12.15 on page 145.).

In addition, *CarSpeedRegulator* owns also two parts: *spm* and *rgm*. The *spm* part specifies an output atomic flow port (port stereotyped with «flowPort») which can relay outside the *outSpeed* data typed as *Integer*. The *rgm* part defines firstly an atomic input flow port (port stereotyped with «flowPort») through which the *inSpeed* data can be relayed from outside (i.e., from its environment). The second port owned by the *rgm* part (the *rp* port) is a message port (stereotype «messagePort» and associated icon "\langle"). This port is typed by the *RegInterface* which defines both a required service and a input signal (see the detailed definition of the interface in Figure 12.15 on page 145).

Figure 12.16 - Example of UML composite classes and parts with specialized MARTE ports

Figure 12.17 - Example of UML component with specialized MARTE ports

12.4.2 Avionics Example

Figure 12.18 illustrates a Trajectory component used in a Flight Management System inspired from an avionics textbook. This component computes a trajectory and generates continuous navigation commands to other equipment. Trajectory depends on three components, defined in related packages, to perform its tasks: FlightPlan, Location, and Database.

Trajectory makes use of flight plan data, as well as the current plane location to perform computations. It explicitly calls the getLocation and getFlightPlan required services, to access these data when needed. These services are defined in the LocationAccess and FlightPlanAccess interfaces, bound to two dedicated message ports.

Trajectory also makes use of performance and fuel consumption parameters stored in its cache. It happens that a pilot changes these parameters, initially stored in the database, when the FMS is in operation. If so, the Database component notifies Trajectory that new parameters need to be taken into account. This information is pushed through an atomic flow port to the Trajectory component. The icon indicates that the direction of the Trajectory flow port is "in". The flow port is typed by a ParameterUpdated signal that contains new parameter data.

When computations are completed, Trajectory generates navigation commands as a data flow specified by the NavCommand flow specification. The data flow is transmitted to external equipment through a dedicated flow port. The icon indicates that the port is typed by a flow specification and therefore it is not atomic.

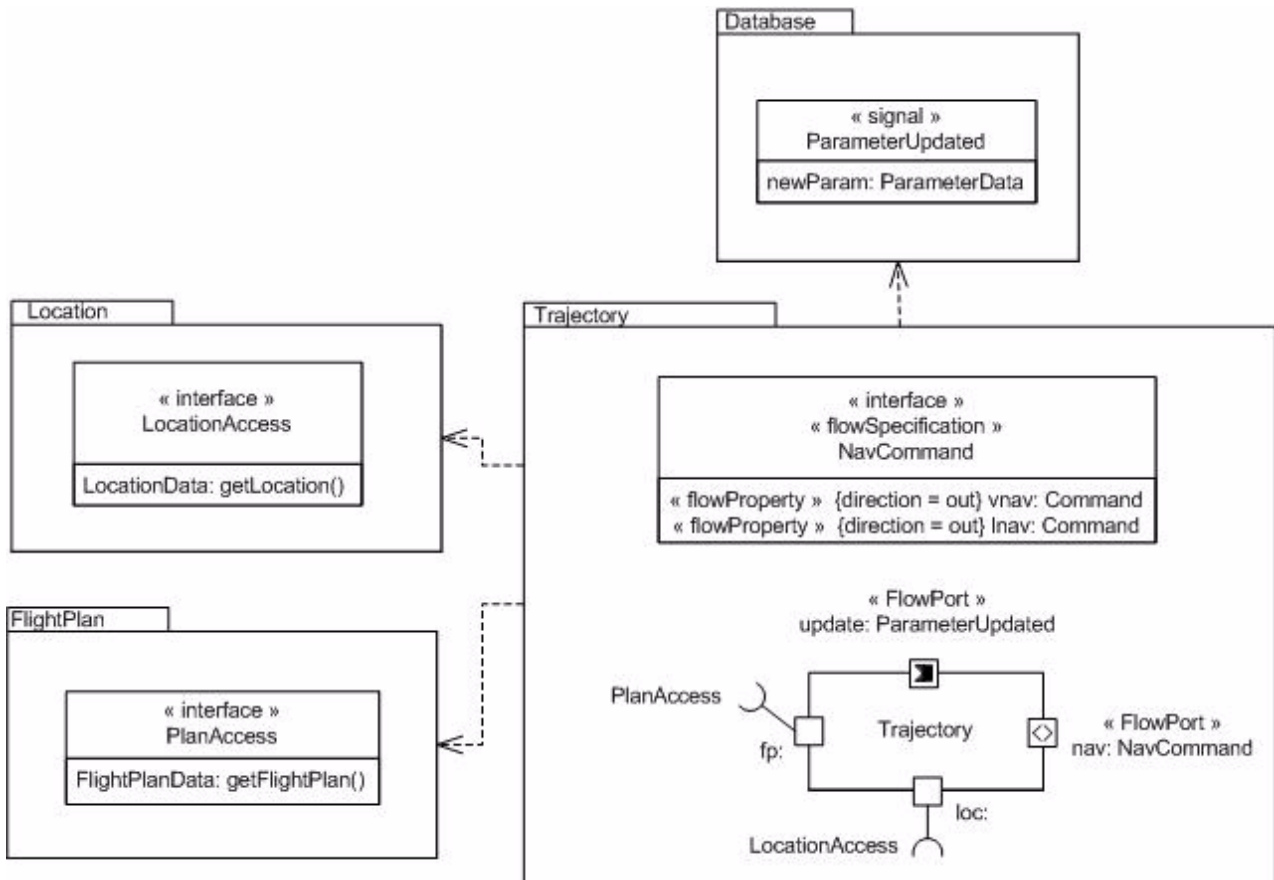

Figure 12.18 - Trajectory component definition

Figure 12.19 illustrates the internal structure of the simple FMS. It shows how the Trajectory component, along with FlightPlan, Location and Database, is used as a part of the FlightManagementSystem composite structure. One can distinguish boundary ports, owned by FlightManagementSystem and defined at the component boundaries. These ports relay incoming data inside a component (e.g., cdsCom, cdsDisplay, irs, radio) or outgoing data to other connected components (e.g., extNav). The other ports indicated in the composite structure relate to component parts (e.g., fp, loc, update, nav, owned by the :Trajectory part). These ports are used to tie parts together using connectors and define a component assembly. Within a component assembly, connected ports need to define compatible types and directions. Message ports need to be typed by a common interface (e.g., PlanAccess), a left-hand port providing this interface (e.g., traj) and a right-hand port requiring this interface (e.g., fp). Flow ports need to be typed by a common flow element or flow-specification (e.g., ParameterUpdated), with opposite directions on the left-hand and right-hand ports (e.g., src and handler).

A boundary port can be connected to a port owned by a part in order to relay a service invocation or a data flow to the component assembly (e.g., cdsDisplay and cds). In that case, port directions are relayed as well.

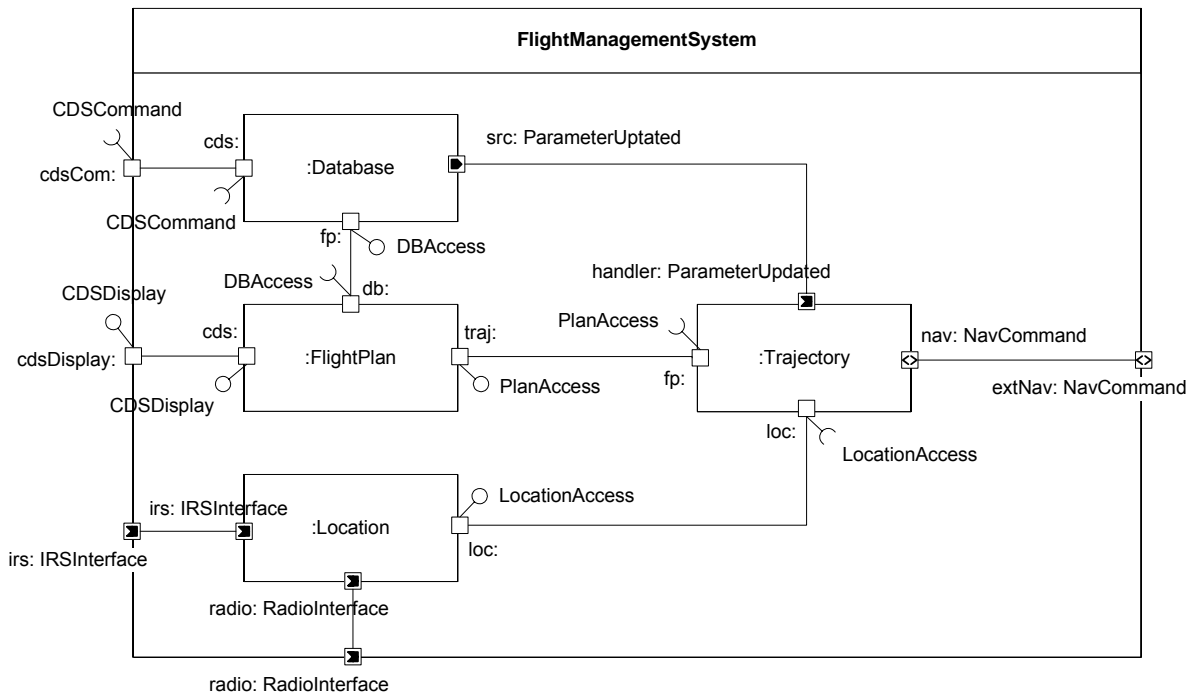

Figure 12.19 - FlightManagementSystem internal structure

Note – Both Figure 12.18 and Figure 12.19 are compatible with the SysML block definition diagrams and internal block diagrams.

13 High-Level Application Modeling (HLAM)

13.1 Overview

Figure 13.1 - Dependencies of the HLAM package

As illustrated by Figure 13.1, the HLAM package of MARTE is depending of both GRM and CoreElements packages, but also on the CoreElements package. The concern of the HLAM package is to provide high-level modeling concepts to deal with real-time and embedded features modeling. In comparison with usual application domains, RT systems (in short RTS) development requires possibilities of modeling on one hand quantitative features such as deadline and period and, in other the hand, qualitative features that are related to behavior, communication and concurrency. The next section will describe a domain model defining the MARTE concepts for RT/E high-level modeling constructs to support both aspects.

13.2 Domain View

One first important issue to deal with when modeling RTE applications is concurrency. In order to handle that feature, this specification proposes the concept of RtUnit as depicted in Figure 13.2. It provides high-level constructs for real-time and embedded application modeling based on the MARTE foundations introduced in Part I (within both CoreElements and GRM packages). An RtUnit is similar to the active object of UML but with a more detailed semantics description. It owns one or several schedulable resources (GRM::Scheduling::SchedulableResource). If its dynamic attribute is set to true, the schedulable resources are created dynamically when required. In other case, the real-time unit has a pool of schedulable resources. When no schedulable resource is available, the real-time unit may either wait indefinitely for a resource to be released, wait for only a given amount of time (specified by its poolWaitingTime attribute), increase its pool thread dynamically to adapt to the demand, or generate an exception.

Hence, a real-time unit may be seen as an autonomous execution resource, able to handle different messages at the same time. It can manage concurrency and real-time constraints attached to incoming messages. An RtUnit is a unit of concurrency that encapsulates in a single entity both the object and the process paradigms, which means that concurrency control is encapsulated within the unit. Any real-time unit can invoke services of other real-time units, or send data flows, without worrying about concurrency issues. Real-time units are some kind of tasks servers that can satisfy several requests from several real-time units at the same time, enabling intra-unit parallelism if necessary. An RtUnit owns also a concurrency and behavior controller for managing message constraints according to its current state and the concurrent execution constraints attached to the messages.

An application owns at least one main RtUnit. Following creation, each real-time unit that has a main (which is indicated by setting the isMain attribute to true) starts invoking a main real-time service, which executes until the real-time unit is terminated. Like any other real-time units, the main service of a main unit may perform explicit receive actions during its execution, in order to accept any received events. A receive action by a real-time unit leads to a direct activation of the appropriate service specification. During the execution of the service, triggered by the receipt of the message, the main service may either be blocked (the so-called "run-to-completion" paradigm), or it may proceed executing concurrently to other real-time service. In this latter case, intra-concurrency is to be available within a real-time unit.

An RtUnit may own one or several behaviors. For each of these behaviors is defined a message queue for saving the messages received by the unit. The size of this message queue may be infinite or limited. In this latter case, the queue size is specified by its maxSize attribute. In addition, an RtUnit owns a specific behavior, called operational mode. This behavior take usually the form of a state-based behavior where states represents a configuration of the RtUnit and transitions denotes reconfigurations of the unit.

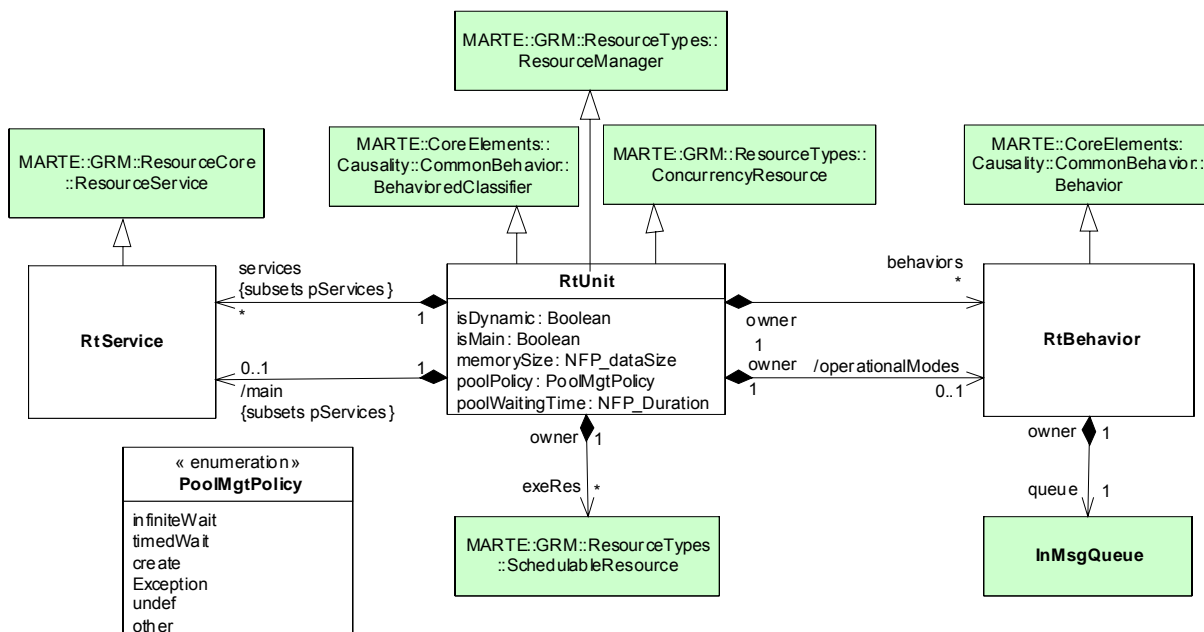

Figure 13.2 - RtUnit of the HLAM package

When modeling for concurrency, it is mandatory to be able to model shared information. For that purpose, it has been introduced the concept of protected passive unit (PpUnit) as denoted in Figure 13.3. Protected passive units specify their concurrency policy either globally for all of their provided services (concPolicy attribute), or locally through the concPolicy attribute of an RtService. The execution kind of a protected passive unit is either immediateRemote or deferred. In both cases, the execution is remote, i.e., it uses a schedulable resource of the real-time unit that invokes the service provided by the protected passive unit.

Figure 13.3 - PpUnit of the HLAM package

The incoming message queue of a real-time unit plays the role of the broker for its schedulable resources. The possible scheduling policies defined within MARTE are specified by the MARTE::GRM::Scheduling::SchedPolicyKind enumeration. The size of the message queue may be either infinite or limited. In the latter case, its size is specified through its queueSize attribute. Additionally, a message queue can also specify the maximal size of the message (msgMaxSize attribute) that may be received.

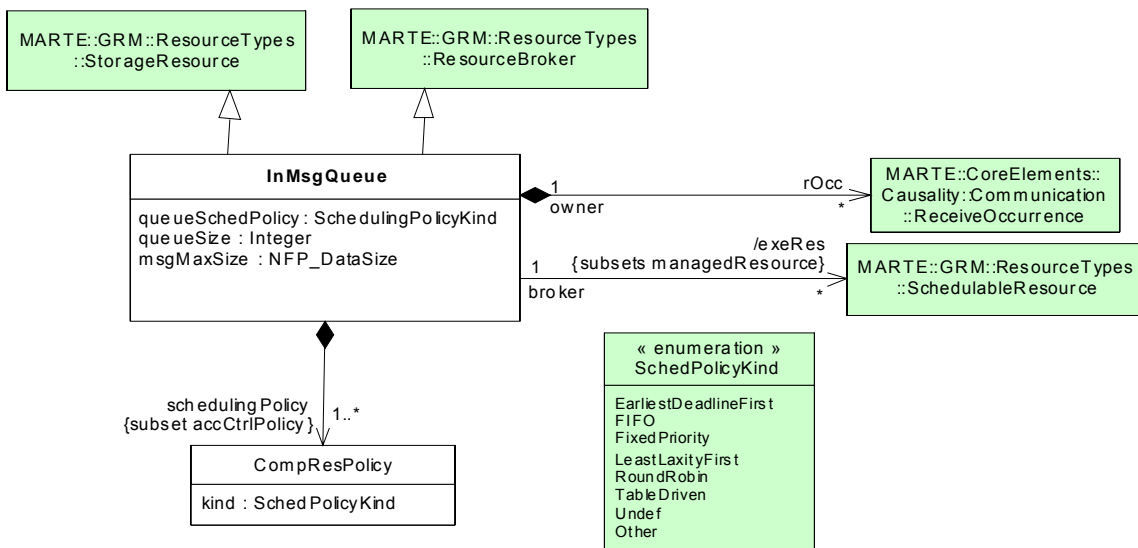

Figure 13.4 - InMsgQueue of the HLAM package

As shown in Figure 13.2 and Figure 13.3, real-time units and protected passive units may provide real-time services. In the case of the protected passive units, as they use the schedulable resource of invoking real-time units, it has to be specified the concurrency policy of the service (concPolicy attribute). The execution of a real-time service may be declared as atomic and it is also possible to specify how the execution is handled by the unit through the exeKind attribute. The service execution may be deferred (i.e. save in a queue of a behaviour of the unit) or immediate. In this case, in a real-time unit, the execution may be done in the context of the calling unit (i.e., remote execution) or in the context of the unit receiving the message (i.e., local execution). In case of a protected passive unit, the remote case does

not apply. Finally, a real-time service may specify a real-time feature and a concurrency policy. Both these information may be used by the internal controllers of real-time units and protected passive units to control the execution of their services.

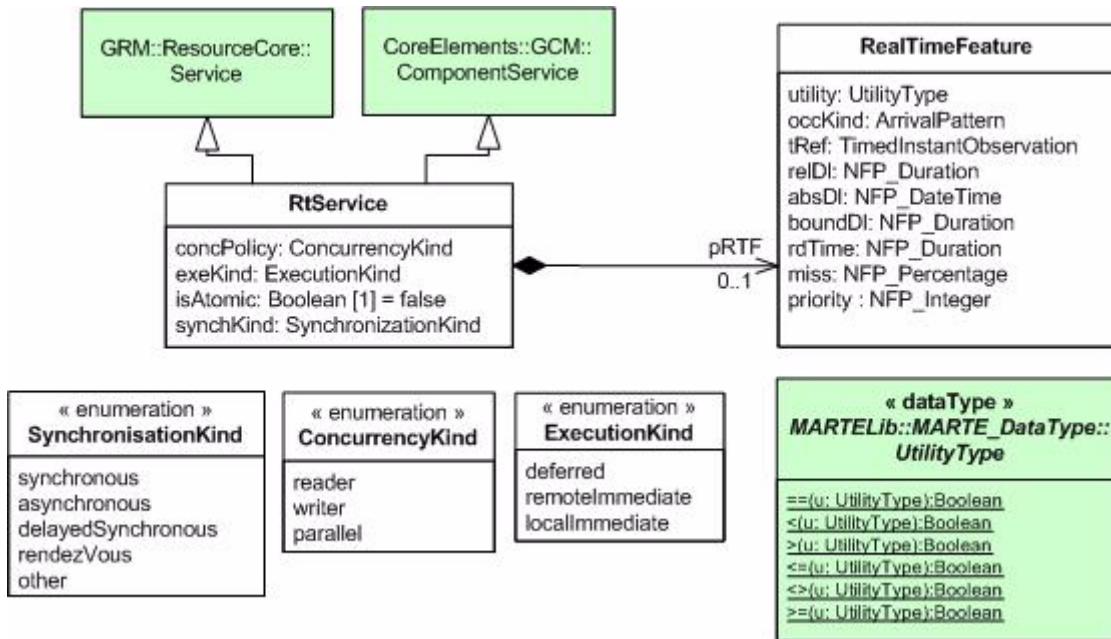

Figure 13.5 - RtService of the HLAM package

One other important qualitative feature to handle in this domain concerns the communication aspects. In UML, communications are initiated by executing specific actions such as call actions. Here it is introduced the concept of real-time action (specialization of the action concept introduced in the MARTE::CoreElements package). Real-time action can specify real-time features such as a deadline or period (see details of the ArrivalPattern data type introduced in the MARTE Model Library). It can also describe the size of the message generated when executing or the kind of synchronization (synchKind attribute). Finally, a real-time action execution may be defined as atomic.

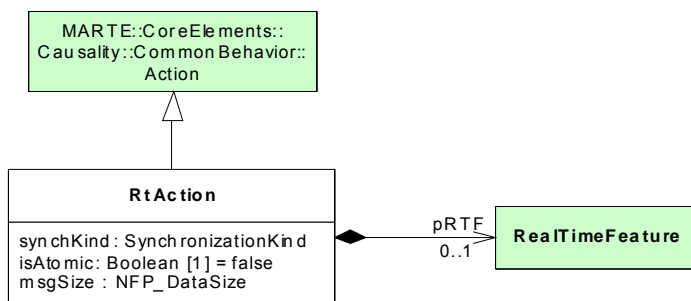

Figure 13.6 - RtAction of the HLAM package

This section formalizes a specific model of computation aligned on the notion of active object defined in UML. It is applicable for asynchronous / event-based approaches to real-time and embedded application design.

Other approaches and models of computation exist in the real-time and embedded domain (e.g., synchronous objects). The MARTE specification does not explicitly address these models at this time. However, the framework introduced in Part I provides the foundations to specify alternative models of computation as an extension to the specification. Making use of the NFP, Time and GRM packages, interested parties are able to formalize user-defined models of computation that rely on the same semantics foundation. It provides the ability to leverage existing MARTE capabilities along with this specific model.

13.3 UML Representation

This section describes the MARTE HLAM sub-profile. This latter contains all required UML extensions to support the concepts denoted in the previous domain model.

Figure 13.7 - The MARTE HLAM sub-profile

Figure 13.12 - RtService of the MARTE::HLAM sub-profile

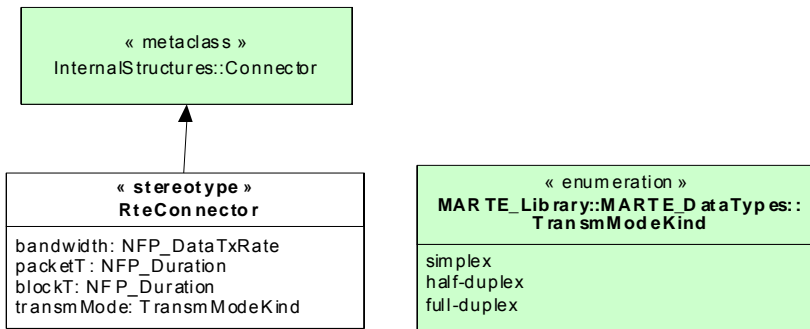

Figure 13.13 - RteConnector of the MARTE::HLAM sub-profile

13.3.2 Profile Elements Description

13.3.2.1 CallConcurrencyKind

The CallConcurrencyKind enumeration maps the CallConcurrencyKind domain element (section F.7.1) denoted in Annex F.

This enumeration defines the kind of concurrency policy applied to a protected passive unit.

Literals

- sequential only one schedulable resource at a time can access a feature of a PpUnit. The PpUnit do not provide in this case access control mechanism, it is up to the client to deal with potential concurrent conflicts.
- guarded a schedulable resource at a time can access a feature of a PpUnit while concurrent ones are suspended.
- concurrent multiple schedulable resources at a time can access a PpUnit.

13.3.2.2 ConcurrencyKind

The ConcurrencyKind enumeration maps the ConcurrencyKind domain element (section F.7.3) denoted in Annex F.

This enumeration defines the kinds of concurrency of a behavioral feature.

Literals

- reader the behavioral feature execution has no side effects (i.e. it does not modify the state of the object, or the values of its properties).
- writer the behavioral feature execution may have side effects.
- parallel the behavioral feature execution may be done in parallel of any kind of service.

13.3.2.3 ExecutionKind

The ExecutionKind enumeration maps the ExecutionKind domain element (section F.7.4) denoted in Annex F.

This enumeration defines the kind of execution of a behavioral feature.

Literals

- deferred event occurrence matching the service invocation is saved in the queue of behavior attached to the object.
- remoteImmediate the execution is performed immediately with schedulable resource of the calling object.
- localImmediate the execution is performed immediately with a schedulable resource of the called object.

13.3.2.4 PoolMgtPolicyKind

The PoolMgtPolicyKind enumeration maps the PoolMgtPolicy domain element (section F.7.4) denoted in Annex F.

This enumeration has been introduced in the profile to define the concurrency pool management policy of the real-time units.

Literals

- infiniteWait if the pool is empty, the real-time unit waits indefinitely until a schedulable resource will be released.
- timedWait if the pool is empty, the real-time unit waits for bound time until a schedulable resource will be released. At the end of the waiting time, if no schedulable resource have released, an exception is raised.
- dynamic if the pool is empty, the real-time unit creates a new schedulable resource and adds it to the pool.
- exception if the pool is empty, the real-time unit raise an exception.
- other

13.3.2.5 PpUnit

The PpUnit stereotype maps the PpUnit domain element (section F.7.7) denoted in Annex F.

Protected passive units specify their concurrency policy either globally for all of their provided services (concPolicy attribute), or locally through the concPolicy attribute of the RtService. The execution kind of a protected passive unit is either immediateRemote or deferred. In this latter case, the execution is also remote, i.e. it uses the schedulable resource of the real-time unit invoking the service to the protected passive unit.

Extensions

- BehavedClassifier (from UML::CommonBehavior::BasicBehaviors).

Attributes

- concPolicy: CallConcurrencyKind [0..1]
kind of concurrency policy applied to the behavioural feature of the PpUnit. CallConcurrencyKind is the enumeration defined in the UML2. Its literal values may be as defined in UML: sequential, guarded or concurrent.
- memorySize: NFP_DataSize
amount of static memory required for each instance of the protected passive unit to be placed in an application.

13.3.2.6 RtAction

The RtAction stereotype maps the RtAction domain element (section F.7.8, p. 495) denoted in Annex F.

InvocationActions and BehavioralFeatures, stereotyped with RtAction, gain the additional following attributes of "real-time" constraints.

Extensions

- InvocationAction (from UML::BasicBehaviors).
- BehavioralFeature (from UML::Kernel).

Attributes

- synchKind: SynchronizationKind
synchronization mechanism associated to the communication action.
- isAtomic: Boolean [1] = false
when true, implies that the RtAction executes as one indivisible unit, non-interleaved with other RtActions.
- msgSize: NFP_DataSize
size of a message generated when executing an action.

13.3.2.7 RtBehavior

The RtBehavior stereotype maps both RtBehavior (section F.7.9) and InMsgQueue (section F.7.5) domain elements denoted in Annex F.

This stereotype matches to both the RtBehavior and the InMsgQueue domain concepts defined in Annex F.

A RtBehavior owns implicitly a queue to store the messages received by the real-time unit. If its owning unit is a real-time unit, a schedulable resource, as soon as it gets available, can be assigned to handle a message.. The possible scheduling policies defined within MARTE are specified by the SchedulingPolicyKind enumeration. The size of the

message queue may be either infinite or finite. In the latter case, its size is specified through its `queueSize` attribute. Additionally, a message queue can also be specified the maximal size of the message (`msgMaxSize` attribute) that may be received.

Extensions

- Behavior (from UML::CommonBehaviors)

Attributes

- `queueSchedPolicy`: SchedPolicyKind [0..1] queue policy of the behaviour.
- `queueSize` : Integer [0..1] queue size.
- `msgMaxSize` : NFP_DataSize [0..1] maximal size of the messages acceptable in the queue.

Constraints

[1] If the owner of the `RtBehavior` is a protected passive unit both `queueSchedPolicy` and `queueSize` are not applicable.

13.3.2.8 RtFeature

The `RtFeature` stereotype maps the `RealTimeFeature` domain element (section F.7.10) denoted in Annex F.

The `RtFeature` stereotype is used to annotate model elements with real-time features according to the properties defined within this stereotype. This stereotype may be also used in other contexts than `RtUnit` and `PpUnit`.

Extensions

- Action (from UML::Kernel)
- BehavioralFeature (from UML::Kernel)
- Message (from UML::BasicInteractions)
- Signal (from UML::Communication)
- Behavior (from UML::BasicBehaviors)

Attributes

- `utility`: UtilityType [0..1]
importance features specification. This property is typed by the `UtilityType` data type defined in the `MARTE_Library`. This type is abstract and it is to the user to define its own specialized utility type according to its needs.
- `occKind`: ArrivalPattern [0..1]
arrival pattern specification.
- `tRef`: TimedInstantObservation [0..1]
time reference used for relative timing properties.
- `relDI`: NFP_Duration [0..1]
relative deadline specification.
- `absDI`: NFP_DateTime [0..1]
absolute deadline specification.

- boundDI: NFP_Duration [0..1]
relative deadline.
- rdTime: NFP_Duration [0..1]
minimal ready time.
- miss: NFP_Percentage [0..1]
percentage of acceptance for missing the deadline.
- priority : NFP_Integer [0..1]
priority specification.

13.3.2.9 RtService

The RtService stereotype maps the RtService domain element (section F.7.12) denoted in Annex F.

. BehavioralFeatures, stereotyped with RtService, gain the additional following attributes of "real-time" constraints. The RtService stereotype may be applied on one BehavioralFeature independently of the fact that the containing classifier to be either a RtUnit or a PpUnit.

Extensions

- BehavioralFeature (from UML::Kernel)

Attributes

- concPolicy: ConcurrencyKind [0..1] concurrency property of the service.
- exeKind: ExecutionKind [0..1] execution nature property of the service.
- isAtomic: Boolean [1] = false when true, implies that the RtService executes as one indivisible unit, non-interleaved with other RtService.
- synchKind: SynchronizationKind [0..1] synchronization mechanism of the service.

13.3.2.10 RtUnit

The RtUnit stereotype maps the RtUnit domain element (section F.7.13) denoted in Annex F.

An RtUnit is similar to the active object of UML but with a more detailed semantics description. It owns at least one schedulable resource, but can also have several ones. If its dynamic attribute is set to true, the schedulable resources are created dynamically when required. In other case, the real-time unit has a pool of schedulable resources. When no schedulable resources are available in the possible, the real-time unit may either wait indefinitely for a resource to be released, or wait only a given amount of time (specified by its poolWaitingTime attribute), or increase its pool thread dynamically to adapt to the demand, or generate an exception. An RtUnit may own behaviors that have one message queue for saving the messages received by the unit. The size of this message queue may be infinite or finite. In this latter case, the queue size is specified by its maxSize attribute. In addition, an RtUnit owns a specific behavior, called operational mode. This behavior take usually the form of a state-based behavior where states represents a configuration of the RtUnit and transitions denotes reconfigurations of the unit.

Extensions

- BehavoredClassifier (from UML::CommonBehavior::BasicBehaviors)

Attributes

- **isDynamic**: Boolean [1] = true
if true, it denotes that the real-time unit creates dynamically the schedulable resource required to execute its services. If false, the real-time unit owns a pool of schedulable resources to execute its services.
- **isMain**: Boolean [0..1]
if true, the real-time unit is a main unit of the application.
- **memorySize**: NFP_DataSize
amount of static memory required for each instance of the real-time unit to be placed in an application
- **poolSize**: Integer [0..1]
size of the schedulable resource pool of a real-time unit.
- **poolPolicy**: PoolMgtPolicyKind [0..1]
kind of pool policy adopted by a real-time unit.
- **poolWaitingTime**: NFP_Duration [0..1]
maximal time a real-time unit waits for a schedulable resource to be released in case of pool management policy set to `timedWait`.
- **operationalMode**: Behavior [0..1]
behavior owned by the real-time unit and denoting the operational modes of the real-time unit.
- **main**: Operation [0..1]
main operation of the real-time unit.
- **memorySize**: NFP_DataSize [0..1]
amount of static memory required for each instance of the real-time unit to be placed in an application.

Constraints

- [1] If `isDynamic` is true, the real-time unit do not owns a pool of schedulable resources. Hence, `poolSize`, `poolPolicy` and `poolWaitingPolicy` are not applicable.
- [2] A main real-time unit has to own a main operation.

13.3.2.11 SynchronisationKind

The `SynchronisationKind` stereotype maps the `SynchronisationKind` domain element (section F.7.14) denoted in Annex F. This enumeration defines the kinds of synchronization mechanism for real-time actions.

Literals

- **synchronous** the action waits the end of the client execution before continuing to execute.
- **asynchronous** the action does not wait the end of the client execution before continuing to execute.
- **delayedSynchronous** the client action continues to execute and synchronize later when the client will return a value.
- **rendezVous** the client waits for the client to start executing.

13.4 Examples

13.4.1 Notational examples

Figure 13.15 describes a class diagram of a very simple cruise control system that is used to illustrate the usage of MARTE::HLAM sub-profile. Both CruiseController and ObstacleDetector are real-time units. The former create dynamically schedulable resources to handle the execution of its services, and the latter has a pool of 10 schedulable resources.

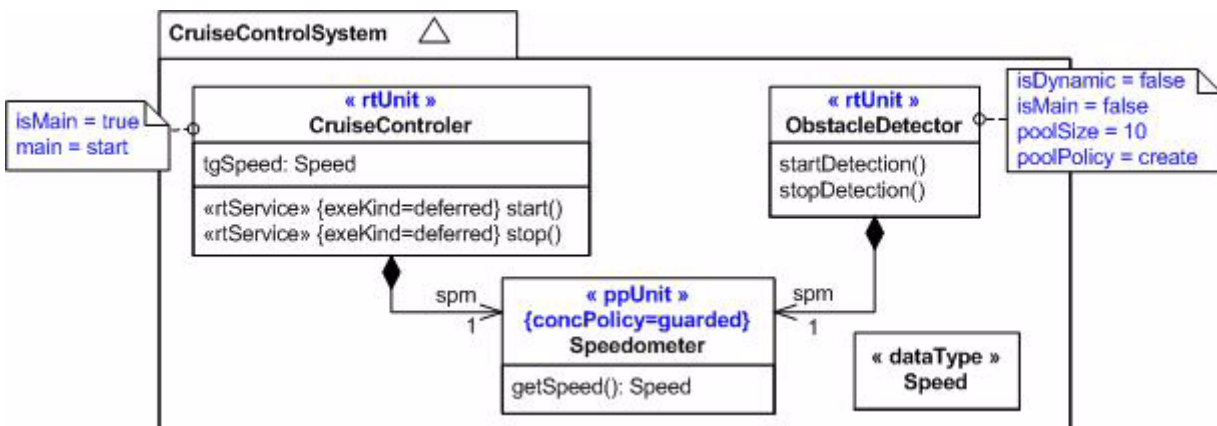

Figure 13.14 - A very simple cruise control model

Figure 13.6 shows an example of call action with a deadline real-time feature specification. The generated message is aperiodic. Its time reference is denoted by the instant observation to. This latter denotes the start execution time of the action. The specified deadline is 10 ms and the acceptable rate of deadline missing is 1%.

Figure 13.15 - An example of call action with a deadline real-time feature

Figure 13.17 shows an example of call action with a priority real-time feature specification.

Figure 13.16 - An example of call action with a priority real-time feature

Figure 13.18 shows an example of real-time feature specification within a sequence diagram.

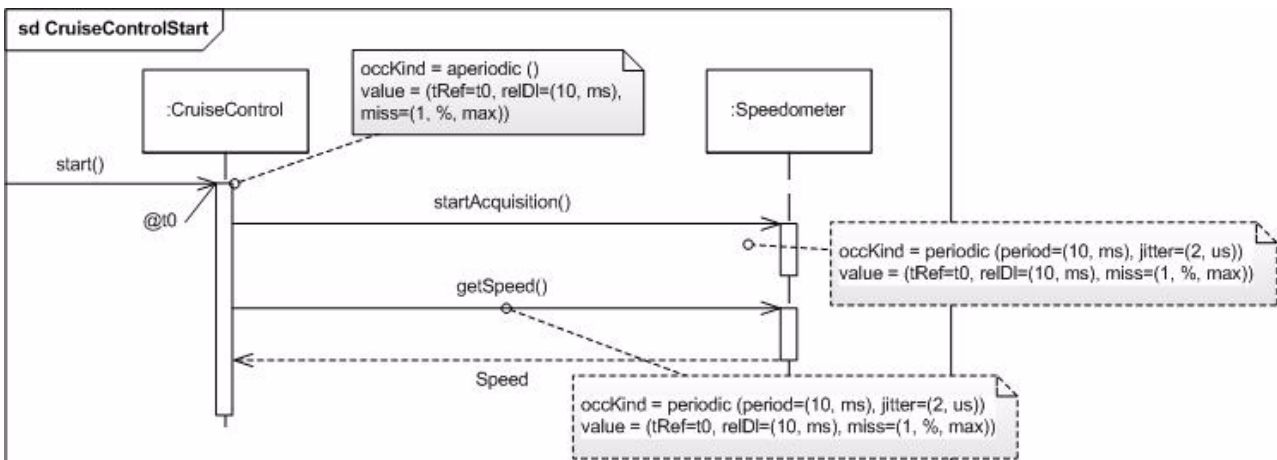

Figure 13.17 - Examples of real-time feature within sequence diagrams

13.4.2 Avionics example

In this example, we make use of components introduced in the avionics example of the General Component Model chapter. We refine these components by applying the real-time characteristics introduced in this chapter. We consider Trajectory, Location, FlightPlan and Database as passive components that require to be allocated on execution resources to be set in operation. Figure 13.19 illustrates elements of the Location package used for communicating with Trajectory. Location is a passive component (e.g. Lw-CCM), which provides a real-time service called getLocation through its LocationAccess interface. The operation carries a "rtService" stereotype that indicates the concurrency kind (reader), the execution kind (deferred) and the synchronization kind (delayedSynchronous). The operation also carries a "rtFeature" stereotype that indicates additional real-time features, such as the priority (P1), the occurrence kind (10 ms period, 2 ms jitter), the relative deadline (3 ms), as well as the acceptable deadline miss ratio (1% i.e. a hard deadline). Defining these features at a service level is used as a contract defined between ports that provide and require the service. The characteristics are applicable whatever the service invocation context or action.

The Location package also introduces a protected passive unit, called LocationData and stereotyped "ppUnit". It is used to transmit data from the Location to the Trajectory component. When initialized, Location instantiates a LocationData object and keeps it periodically updated, based on the IRS and radio signal received. Trajectory concurrently accesses to the same object as a reader, invoking the getLocation real-time service every 10 ms. LocationData implements a sequential access policy that ensures integrity by preventing readers and writers to concurrently access to the same data.

Figure 13.18 - Real-time characteristics defined on elements of the Location package

Figure 13.20 illustrates the main behavior of the Trajectory component, called computeTrajectory. This activity defines a series of four periodic actions triggered every 10 ms. At the beginning of the period, two actions are concurrently activated: a CallServiceAction invokes the getLocation real-time service, while another CallServiceAction invokes the getFlightPlan real-time service. Real-time features defined on getLocation apply here and there is no need to redefine these. Real-time features can be also defined at an action level, using the "rtAction" and "rtFeature" stereotypes, as illustrated by the getFlightPlan, performComputation and generateCommand service call actions.

Both getLocation and getFlightPlan service calls are delayed synchronous. Results shall be received and control flows need to be synchronized (with a 3 ms deadline constraint) before the trajectory computation begins with the invocation of the internal performComputation operation (synchronous, with a 4ms deadline constraint). Resulting commands can be generated and relayed through the nav flow port owned by Trajectory, with the invocation of the internal generateCommand operation (synchronous, with a 1ms deadline constraint).

Figure 13.19 - Main behavior of the Trajectory component

Figure 13.21 illustrates another behavior owned by the Trajectory component. This activity is composed of aperiodic actions triggered upon a reception of a `ParameterUpdated` signal, sent by the Database component. When the signal is received, the deadline to handle parameter change is 1ms with a miss ratio of 20% (i.e. a soft deadline). The `updateParam` service call action is assigned priority P2. As a consequence, this operation will be invoked when the `computeTrajectory` activity is completed.

Figure 13.20 - A trajectory behavior that handles events from Database

Figure 13.22 illustrates a particular execution of the Trajectory behaviors within a period, based on information presented in previous figures. It shows a possible series of interactions between components in that context. The period starts at $t0[i]$. A message is sent from Trajectory to Location, representing the `getLocation` service call in this sequence diagram. The message is be stereotyped as a real-time feature, indicating information such as period and deadline. Other characteristics (e.g., synchronization kind) are implied from real-time features defined on a real-time actions or services. A message is also sent from Trajectory to FlightPlan, representing the `getFlightPlan` service call.

Trajectory computation begins when both `LocationData` and `FlightPlanData` objects are returned (this internal behavior is not shown in this diagram). The sequence of actions used to compute the trajectory and generate the navigation commands shall end by $t1[i]$, 8 ms after the beginning of the period. This allows 2 ms in order to handle aperiodic signals. An aperiodic signal arriving before $t1[i]$ implies that its resulting processing will be delayed. The `updateParam` service call action has a lower priority than the other actions. In this execution scenario, the signal `ParamUpdated` is received after the Trajectory component completed its computation. Therefore, the parameter update can be immediately processed.

Figure 13.21 - A Trajectory execution scenario within a period

Note: We assume here that all the components rely on a same global clock.

14 Detailed Resource Modeling (DRM)

The objective of this chapter is to provide specific modeling artifacts to be able to describe both software and hardware execution supports. It specializes generic concepts offered by the previous General Resource Modeling (GRM) chapter. As depicted in Figure 14.1, the DRM chapter consists of both packages:

- The Software Resource Modeling (SRM) package, which intends to describe application programming interfaces of software multi-tasking execution supports.
- The Hardware Resource Modeling (HRM) package, which intends to describe hardware execution supports, through different views and detail levels.

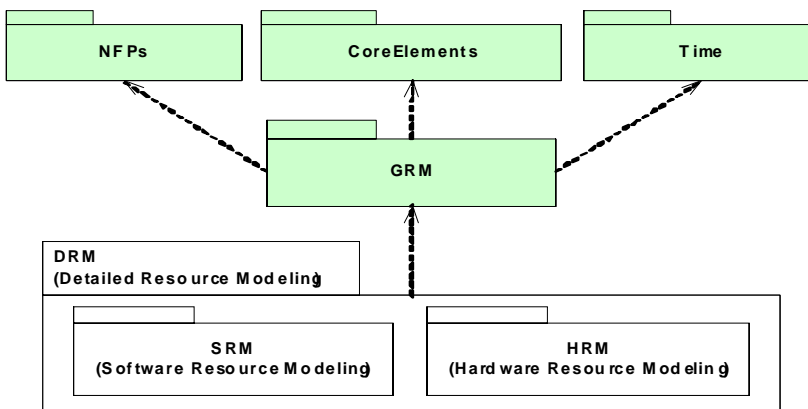

Figure 14.1 - Detailed Resource Modeling (DRM) overview

14.1 Software Resource Modeling (SRM)

14.1.1 Overview

There are mainly two approaches to design software real-time and embedded (RTE) applications: the sequential-based design approach (also called loop-design) and the multitask-based design approach. The former approach consists in designing applications as a set of ordered sequential actions, whose order is pre-calculated in order to satisfy the real-time features. The multitask-based method aims at designing applications as a set of units executing concurrently and interacting (i.e., communicating and synchronizing) via specific mechanisms provided by a specific execution support. That support is in charge of real-time and embedded features (e.g., time constraints, determinism and memory footprint). It provides a set of resources and services through its application programming interface (API). That API may be either standard or specific (proprietary or commercial).

The widespread approach used to design software RTE applications is the multi-tasking-based approach build upon a real-time operating system (RTOS) as the execution support. Hence, The Software Resource Modeling (SRM) chapter specifies a set of modeling artifacts that can be used to describe the structure of such support. More specifically, it is looking to depict software resources and software services describing in multi-tasking (API). Thus, it provides:

- Modeling artifacts to design in a unified way RTOS-like software execution support API through the definition of specific UML profile: the SRM (Software Resource Model) sub-profile.

- Examples of specific UML model libraries using the SRM profile to describe parts of standardized RTOS APIs, such as OSEK/VDX (OS 2.2.2) and ARINC (653-1) standards.

The typical use of the SRM UML profile is the description in a unified way of software multi-tasking API in order to integrate explicitly the execution supports in the design flow (e.g., model library description and model transformation description). The SRM profile is not a new multi-tasking API standard. It provides modeling artifacts to describe such API. Moreover, even if this chapter focuses on RTOS APIs, it is useful not only to describe such support but also to depict specific multi-tasking libraries and more generally multi-tasking framework API (e.g., RTE middleware and RTE virtual machine).

This chapter is structured around a domain model description and its UML representation. The domain model section describes domain concepts. That domain model has been build based on a deep analysis of the main RTOS API standards (SCEPTRE 2, POSIX Issue 6 IEEE std 1003.1, OSEK/VDX 2.2.2, ARINC 653-1), and also of some RTOS (e.g., VxWorks 5.5, RTAI 3.1, QNX ...). The UML representation define the UML extensions required to manipulate the concepts as defined in the domain model and then be able to describe UML model libraries.

14.1.2 Domain View

This domain view is a specialization of the Generic Resource domain model for the purpose of software modelling. Hence, the SRM model specializes resources and services previously defined in that previous chapter. Commonly, multi-tasking software resources relate to:

- Concurrent execution contexts (i.e., parallel execution).
- Interactions between concurrent context both to communicate and to synchronize themselves.
- Brokering of hardware and software resources (e.g., device management and memory management).

Hence, the domain model is organized in four packages: SW_ResourceCore which provide the basic software resource concepts, SW_Concurrency which classifies concurrent execution contexts, SW_Interaction which sorts communication and synchronization resources and SW_Brokering which refers to hardware and software resources management. Figure 14.2 shows the overall package structure.

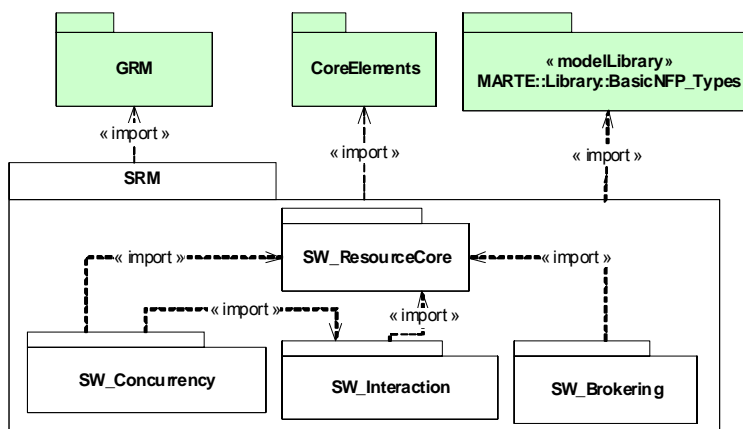

Figure 14.2 - Structure of the SRM modeling framework

The purpose and the content of each package are described briefly in subsequent sections. For more formal semantic details, the reader must refer to the class description (Annex F on page 426).

14.1.2.1 The SW_ResourceCore Package

Figure 14.3 shows the structure of the SW_ResourceCore package.

As a rule, execution supports APIs fulfill real-time and embedded concepts as both a set of types and a set of operations. For example, a kind of concurrency implementation in the POSIX standard is the concept of "thread." Hence, a type named "pthread_t" and an operation named "pthread_create" (i.e., operation that implements the creation of a thread) fulfill POSIX threads. Users make use of those types and operations to implement their applications on the execution support. The SW_ResourceCore package supplies the framework to model both those types and those operations. Types are modeled as SwResource. SwResource inherits from the generic resource concept of the GRM::ResourceCore package. Hence, a SwResource provides by inheritance a set of ResourceServices provided by the GRM package (section 10.2).

In this domain model, there is no distinction between services provided by software resources to the application (for example: a mailbox mechanism allows users to communicate messages) and services provided to manage those resources (for example: the creation and the deletion of a mailbox). A SwResource concept gathers both the resource as such and the manager of that resource. Hence, a SwResource inherits not only from the GRM::ResourceCore::Resource, but also from the GRM::ResourceManagement::ResourceManager.

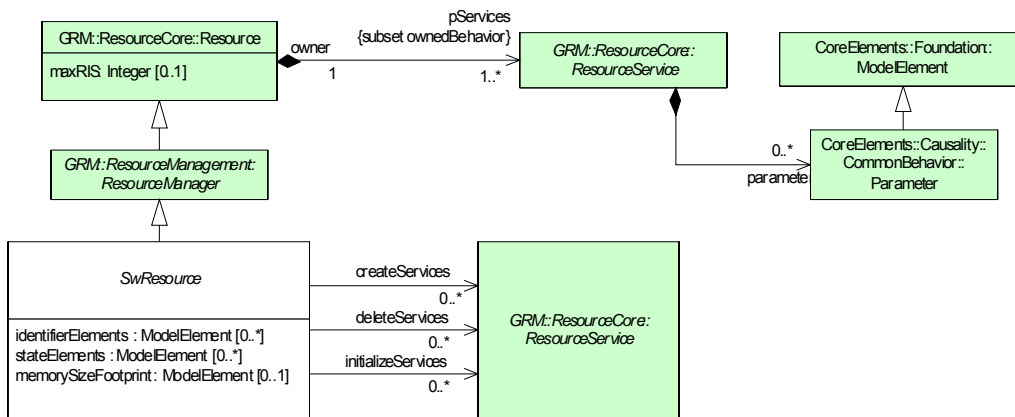

Figure 14.3 - The SW_ResourceCore package overview

A specific software service is the SwAccessService used to access elements. In fact, software resources provide some services to access their characteristics: get and set. Those services may be considered as SwAccessServices. In case of the "set" one, the Boolean attribute "isModifier" may be true.

Figure 14.4 - The SwAccessService

14.1.2.2 The SW_Concurrency Package

Figure 14.5, Figure 14.6, Figure 14.7, Figure 14.8 and Figure 14.9, Figure 14.10 show the structure of the SW_Concurrency package.

The SW_Concurrency package defines SwConcurrentResource which represents entities that compete for computing resources in order to execute sequential part of instructions. They provide an execution context (e.g., stack, interrupts enable/disable and registers) for an execution flow (i.e., sequence of actions). The execution context may be confined to specific memory partition (i.e., virtual address space). Kinds of SwConcurrentResource are interrupt resources and schedulable resources.

An entry point specifies the execution flow associated to a SwConcurrentResource. That entry point is reentrant whether it can be invoked while it is still executing from a previous invocation.

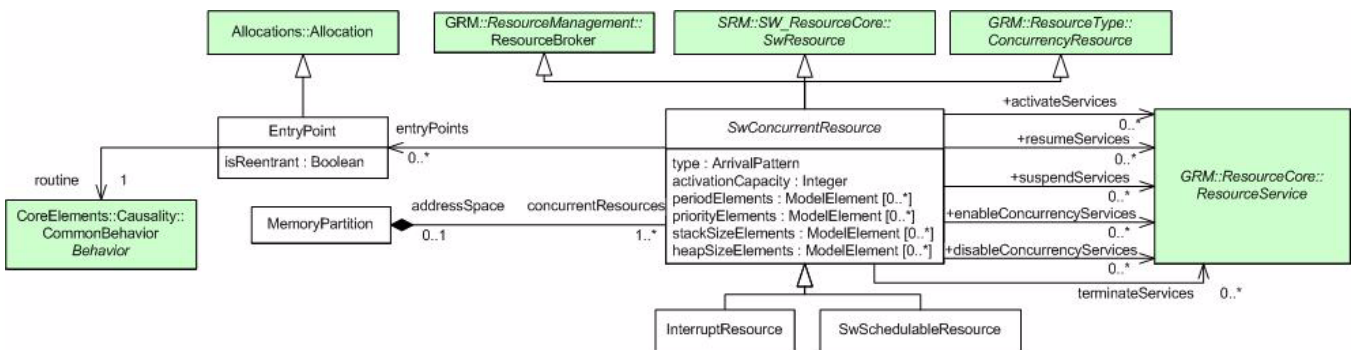

Figure 14.5 - The SwConcurrentResource overview

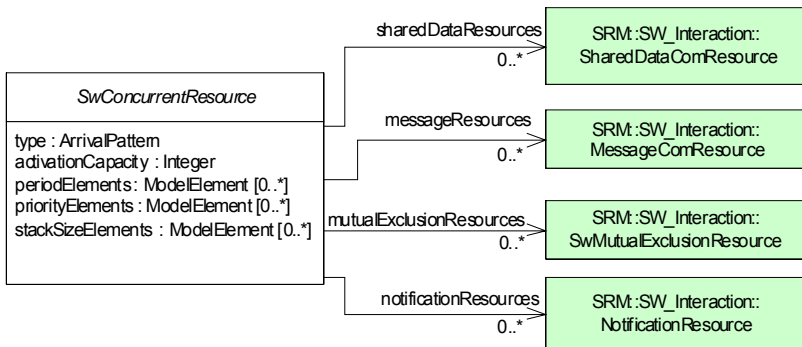

Figure 14.6 - The SwConcurrentResource interactions

Interrupt resources match to the physical processing level. In that execution context, the competition for the processing unit is managed at the physical level by a controller and bypasses the scheduler. Many execution supports provide specific services to manage context of interrupt service routine (ISR) execution (i.e., interrupt entry point). The Interrupt resource deals with both hardware interrupts and exceptions (i.e. software interrupts produced by the control processing unit (CPU) while executing instructions). Exceptions can either be "Processor-detected" exceptions when the CPU detects an anomalous condition while executing an instruction or "Programmed" exceptions (also called software interrupts) when they occur at the request of the programmer. Some example of "Processor-detected" exceptions are faults (divide error, device not ready), traps (breakpoints, debug) and aborts (double fault)).

Figure 14.7 - The Interrupt Resource

A specific class of interruptResource is the alarm one which allows the interrupt service routines (i.e. the alarm entry points) to be connected to a timer and invoked after a one-shot or periodically. A particular software alarm is the watchdog. If the application doesn't succeed in resetting the watchdog, that mean that the system is not functioning properly and the alarm occurs, forcing application to execute the watchdog entry point or to reset the processor.

Figure 14.8 - The Alarm resource

SwSchedulableResources match to the logical processing context. In that context, the competition for the CPU is brokered at the logical level by a software scheduler. Hence, SwSchedulableResources are linked to an explicit software scheduler which determines the order and the timing (i.e., the "schedule") in which those should be executed. Typical examples of SwSchedulableResource are the POSIX Thread, the ARINC-653 Process and the OSEK/VDX Task.

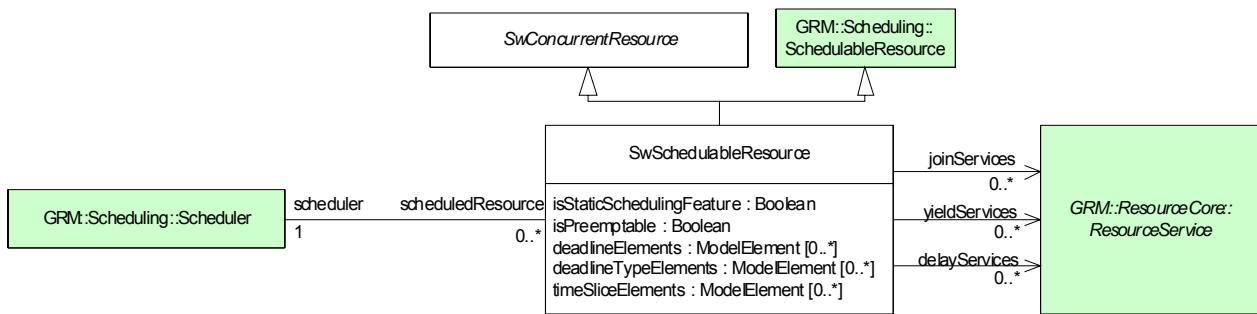

Figure 14.9 - The SwSchedulable resource overview

As explained above, software computing resources may be confined in specific MemoryPartitions. A MemoryPartition represents a virtual address space which insures that each concurrent resource associated to a specific memory partition can only access and change its own memory space.

Figure 14.10 - The MemoryPartition resource

14.1.2.3 The SW_Interaction Package

Figure 14.11, Figure 14.12, Figure 14.13, Figure 14.14, Figure 14.15, Figure 14.16 and Figure 14.17 show the structure of the SW_Interaction package.

In concurrent execution contexts, resources need to interact both to synchronize their actions and to communicate data. Hence, SwSynchronizationResources control execution flows whereas SwCommunicationResources manage data flows.

In any case, resources interact according to a waiting policy. For example, considering a blocked WaitingPolicy, the acquire call part of a mutual exclusion synchronization involves that the caller is blocked in a waiting state (non available for scheduling) until someone release the shared resource. The waiting resources are queued in a waiting queue characterized by a policy and a capacity. Those interactions may be limited to a certain partition of the memory (i.e. isIntraMemoryPartitionInteraction property).

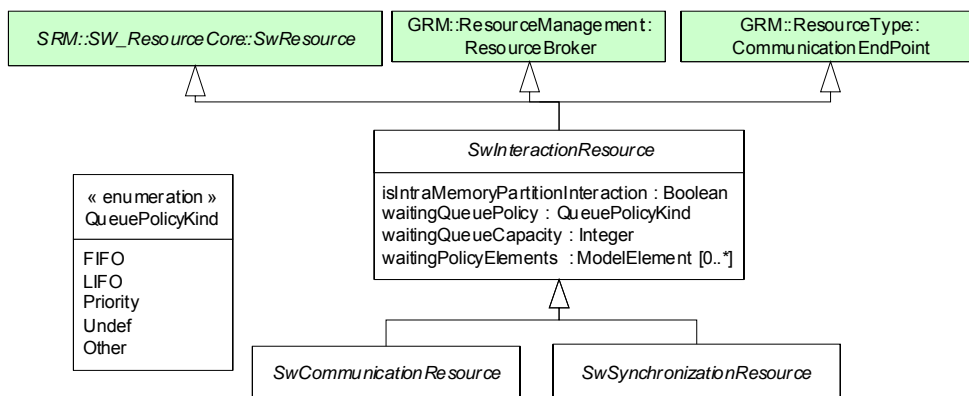

Figure 14.11 - The SW_InteractionResource package overview

To control execution flow, real-time execution supports provide several kinds of synchronization mechanisms: ones to notify event and others to control shared data mutual access. The two corresponding resources are SwMutualExclusionResource and NotificationResource.

Figure 14.12 - The SwSynchronizationResource overview

SwMutualExclusionResource describes resources commonly used to synchronize mutual access to shared data. As examples, Boolean semaphore (one token that anybody can release even if it does not get it), mutex (a Boolean semaphore associated with a concept of ownership : only resource that owns the mutex can release it) and counting semaphore (several token may be got and released) are kind of SwMutualExclusionResource.

Figure 14.13 - The MutualExclusionResource Overview

NotificationResource supports control flow by notifying occurrences of conditions to awaiting concurrent resource. As examples POSIX Signal, OSEK\VDX Event and ARINC-653 Event are NotificationResources. The notified occurrence can be memorized (i.e. memorized in a buffer), bounded (i.e., each occurrence increments a counter) or memoryless (i.e., not memorized in a buffer, hence multiple occurrences are lost).

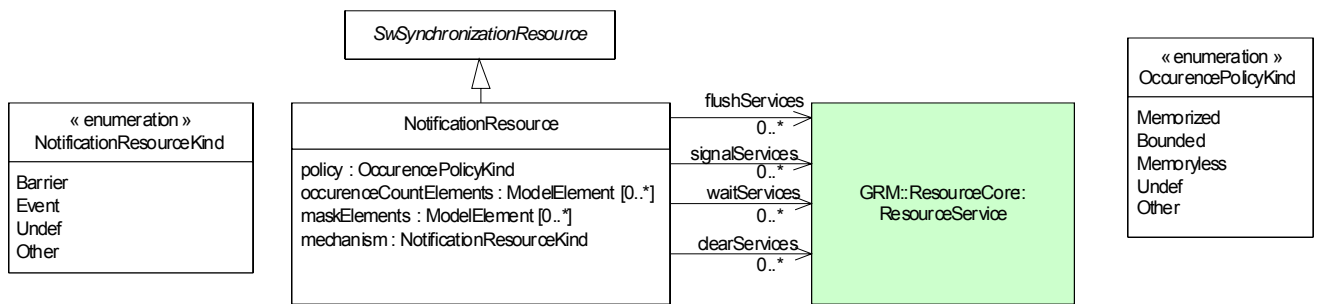

Figure 14.14 - The NotificationResource overview

Commonly, to manage data flows, users can manipulate both shared data and message.

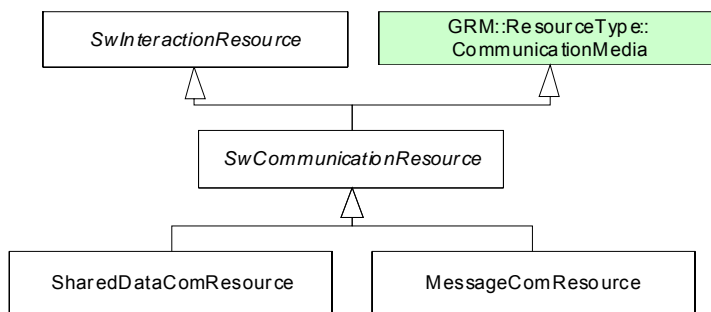

Figure 14.15 - The MessageComResource overview

MessageComResource are artifacts to communicate messages (i.e., a structure of data characterized by for example either a fixed or a dynamic size, a priority, a type of data.) among concurrent resources. Messages may be queued. Common mechanisms are MessageQueue, Blackboard, POSIX Pipe.

Figure 14.16 - The Messaging Communication resource

SharedDataComResource define specific resources used to share the same area of memory among concurrent resources. They allow concurrent resources to exchange safely information by reading and writing the same area in memory.

Figure 14.17 - The shared data communication resource

14.1.2.4 The SW_Brokering package

Figure 11-16 show the structure of the SW_Brokering package.

The SW_Brokering package gathers resources which broke hardware as well as software resources. For example, kind of brokering actions are allocation, hardware device access and so on.

Figure 14.18 - The SW_BrokerResource Package Model

A DeviceBroker (i.e., driver) interfaces peripheral devices to the software execution support. By initializing that resource, user makes devices accessible for software. Commonly, deviceBroker resources are based on file mechanisms. DeviceBroker may be buffered (i.e., in which data is read and written in large chunks and buffered privately).

Figure 14.19 - The DeviceBroker overview

MemoryBroker gathers allocation, mapping (map real memory onto the virtual address ranges used in memory partition) and protection of memory. For example, memory paging and memory swapping techniques impose severe and unpredictable delays in execution time. Thus, applications can use page-locking facilities, such as Lock and UnLock services, to declare that certain blocks of memory must not be paged or swapped.

Figure 14.20 - The MemoryBroker overview

14.1.3 UML Representation

This section contains a definition of each stereotype that is defined for the software resource modeling profile (SRM). The first sub-section describes rationales for matching domain model concepts to UML profile concepts (i.e. sub-profile, stereotypes, tag and constraints). Then, the purpose and the content of each sub-profile are briefly described in a second sub-section. Finally, a third section is dedicated to a detailed description of each stereotype.

As the SRM profile is intended to provide modeling artifacts to describe APIs of multi-tasking execution support, rationales have been made to implement domain model concepts in a UML profile:

- The MARTE::CoreElements::ModelElement metaclass is matched to the UML::Kernel::Classes::TypedElement metaclass. This matched rule allows users to reference as well structural features (for example UML::Kernel::Classes::Property) as behavioral features (for example UML::Kernel::Classes::Parameter). Figure 14.21 shows one example of the SwResource matching.

Figure 14.21 - SRM Matched rule on ModelElement metaclass

- As Associations between ResourceService and SwResource are navigable in one way, the association ends relative to the SwResource metaclass are matched to SwResource stereotype tags. Moreover, the ResourceService metaclass is matched to the UML::Kernel::Classes::BehavioralFeature. In UML, a behavioral feature specifies that an instance of a classifier will respond to a designated request by invoking a behavior. Hence, services described in APIs are kind of behavioral features (i.e. behavior signature). Figure 14.22 shows one example of the SwResource matching.

Figure 14.22 - SRM Matched rule on Association between ResourceService and SwResource

- Associations between domain model concepts are matched both to specific stereotype tags and profile constraints. Figure 14.23 shows one example of the SwConcurrentResource matching.

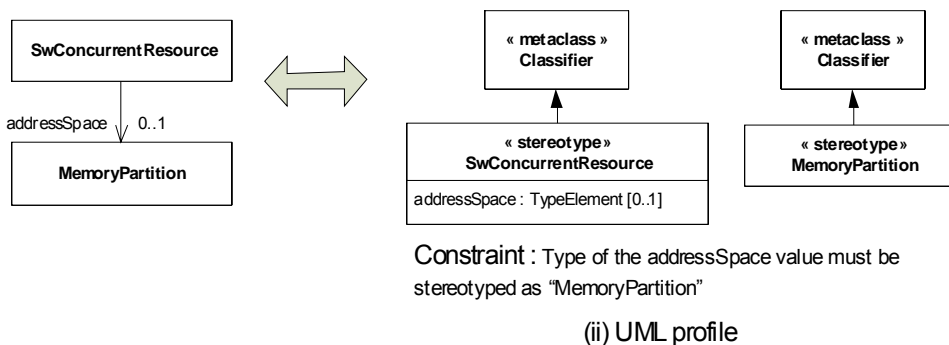

Figure 14.23 - SRM Matched rule on Associations

14.1.3.1 Profile diagrams

Figure 14.24 shows the overall profile structure. The purpose and the content of each sub-profile are described in a subsequent sections.

Figure 14.24 - The SRM profile overview

The SW_ResourceCore sub-profile aims to describe foundations of the SRM profile. It matches to the SW_ResourceCore package (section 14.1.2.1 on page 174).

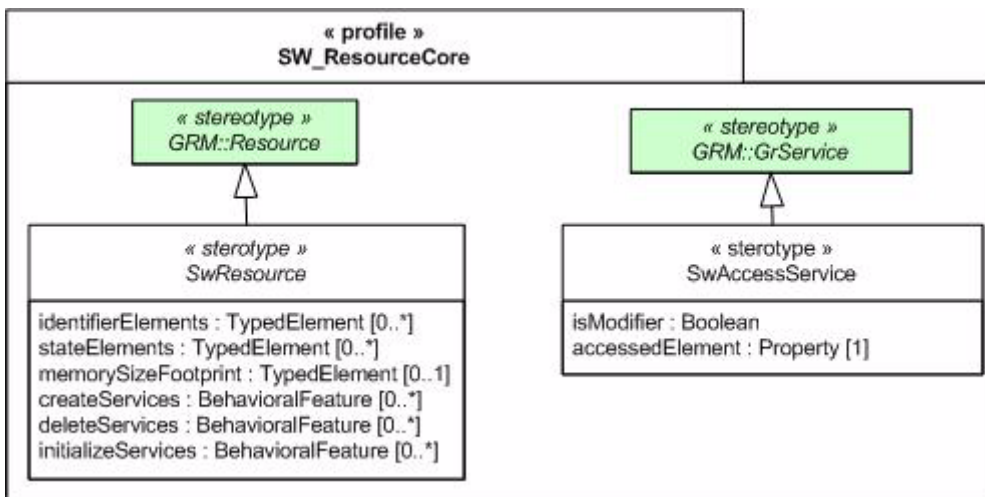

Figure 14.25 - The SW_ResourceCore profile overview

The SW_Concurrency sub-profile matches to the SW_Concurrency package (section 14.1.2.2 on page 175). It aims to provide modeling artifacts to describe software concurrent execution contexts.

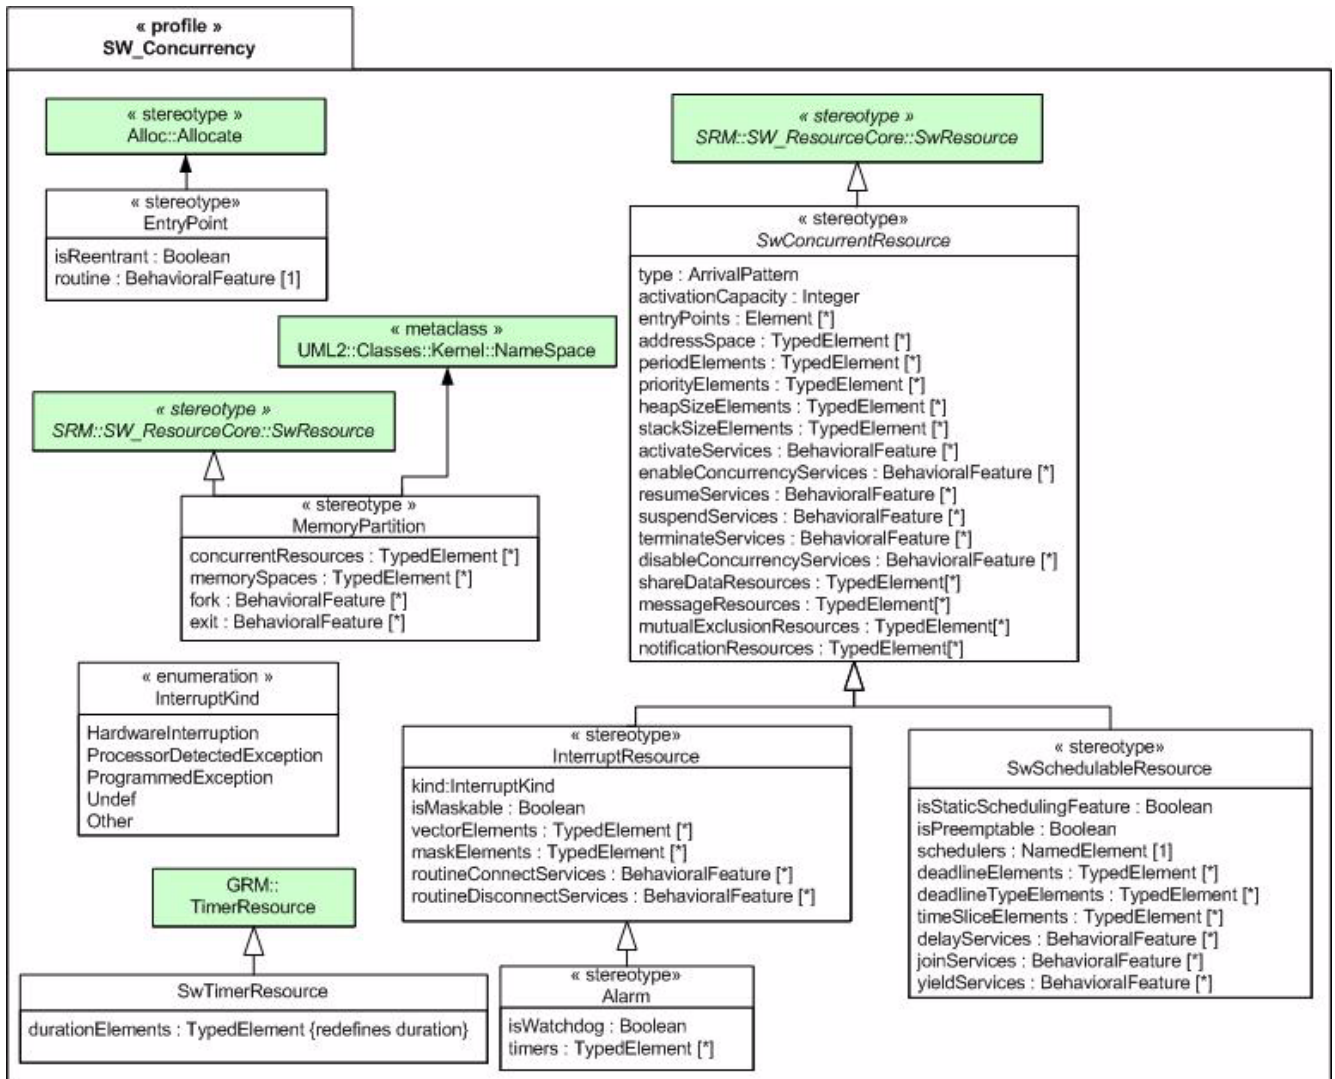

Figure 14.26 - The SW_Concurrency profile overview

The SW_Interaction sub-profile describes communications and synchronizations among concurrent execution contexts. It matches to the SW_Interaction package (section 14.1.2.3 on page 177).

Figure 14.27 - The SW_Interaction profile overview

The SW_Brokering sub-profile matches to the SW_Brokering package (section 14.1.2.4). The SW_Brokering sub-profile describes stereotypes to annotate hardware and software resource management.

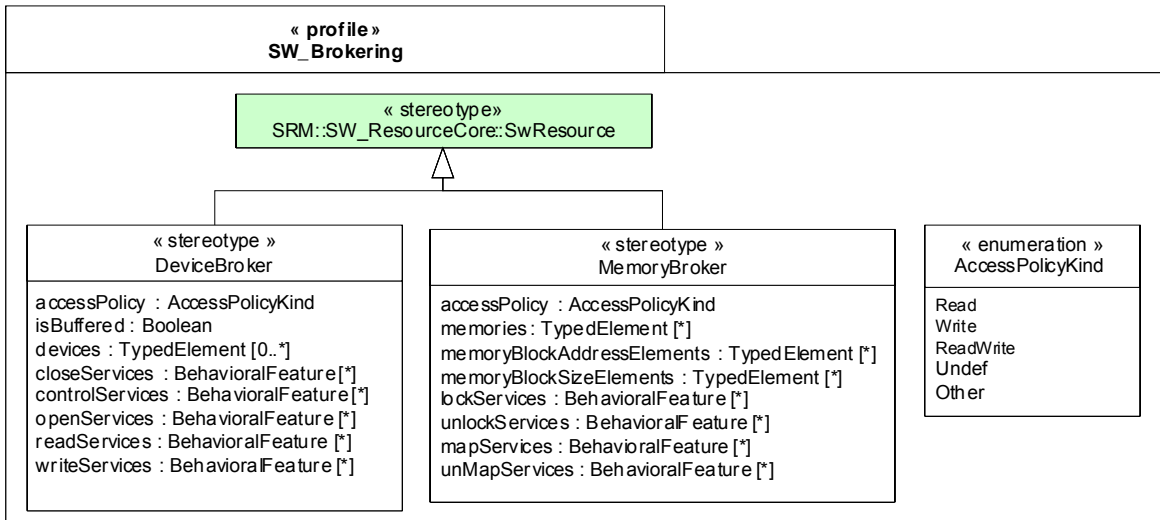

Figure 14.28 - The SW_Brokering profile overview

14.1.3.2 Profile elements descriptions

Alarm (from MARTE::SRM::SW_Concurrency)

This stereotype matches to the domain concept Alarm (section F.8.1) denoted in Annex F.

Alarm resource provides executing context to a user routine, which must be connected to a timer invoked after a one-shot or periodically.

Extensions

- None

Generalizations

- InterruptResource (from SW_Concurrency)

Associations

- None

Attributes

- isWatchdog: Boolean [0..1] specifies if the alarm is a watchdog.
- timers: TypedElement [0..1] specifies the timer which raises the signal to execute the entry-point of the alarm resource.

Constraints

[1] Types of timers values must be stereotyped either as "SwTimerResource".

Notations

The image associated with that stereotype is:

Figure 14.29 - The alarm notation

AccessPolicyKind (from MARTE::SRM::SW_Brokering)

The AccessPolicyKind enumerates common policy to access a resource.

Description

- Read Read access only.
- ReadWrite Read and write access are allowed.
- Write Write access only.
- Undef Undefined policy.
- Other Other user's specific policy.

ConcurrentAccessProtocolKind (from MARTE::SRM::SW_Interaction)

The ConcurrentAccessProtocolKind enumerates common protocol to access mutually a shared resource.

Description

- NoPreemption Lock the concurrency to avoid preemption when a resource is accessing a shared variable.
- PCP Priority Ceiling protocol.
- PIP Priority Inheritance Protocol.
- Undef Undefined policy.
- Other Other user's specific policy.

DeviceBroker (from MARTE::SRM::SW_Brokering)

This stereotype matches to the domain concept DeviceBroker (section F.8.4) denoted in Annex F.

A DeviceBroker (i.e., driver) interfaces peripheral devices to the software execution support.

Extensions

- None.

Generalizations

- SwResource (from SRM::SW_ResourceCore) on page 196

Associations

- None

Attributes

- `accessPolicy`: `AccessPolicyKind` [0..1]
access policy of the device (read, write ...).
- `closeServices`: `BehavioralFeature` [0..*]
services which make the hardware device unavailable from software resources.
- `controlServices`: `BehavioralFeature` [0..*]
services which initialize and broke the device.
- `devices`: `TypedElement` [0..*]
hardware device brokered by the driver.
- `isBuffered`: `Boolean`[0..1]
if true, data is read and written in large chunks and buffered privately.
- `openServices`: `BehavioralFeature` [0..*]
services which establish the connection between a device and the resource. This service makes available the device to software resources.
- `readServices`: `BehavioralFeature` [0..*]
services which read data from the device.
- `writeServices`: `BehavioralFeature` [0..*]
services which write data to the device.

Constraints

[1] Types of devices values must be stereotyped either as "DeviceResource" or as "DeviceBroker" sub-Stereotype.

Notations

The icon associated with that stereotype is:

Figure 14.30 - The deviceBroker notation

EntryPoint (from MARTE::SRM::SW_Concurrency)

This stereotype matches to the domain concept EntryPoint (section F.8.5) denoted in Annex F.

The EntryPoint supply the routine (i.e., operations) executed in the context of the Sw ComputingResource.

Extensions

- Allocate (from Alloc).

Generalizations

- None.

Associations

- None.

Attributes

- isReentrant: Boolean [0..1]
specifies if a single copy of the routine instructions in memory can be shared by multiple concurrent resource. If true, instructions described in the routine could be called from multiple concurrent resource contexts simultaneously without conflict.
- routine: BehavioralFeature [1]
specifies the routine which has to be executed in the context of the software computing resource.

Constraints

- None

InterruptResource (from MARTE::SRM::SW_Concurrency)

This stereotype matches to the domain concept InterruptResource (section F.8.6) denoted in Annex F.

InterruptResource defines an executing context to execute user-delivered routines (i.e., entry point) further to hardware or software asynchronous signals.

Extensions

- None

Generalizations

- SwConcurrentResource (from SRM::SW_Concurrency) on page 193

Associations

- None

Attributes

- kind: InterruptKind [0..1]
specifies the kind of interrupt.
- isMaskable: Boolean [0..1]
interrupts can either be maskable or not. Only few critical signals raise non maskable interrupts. The control processor unit (CPU) always recognizes those. Maskable interrupts can be in two states: unmasked (i.e. recognized by the CPU) or masked (i.e. ignored by the control unit). For example, a schedulable resource can explicitly mask maskable interrupts to avoid its pre-emption in some code sections.
- maskElements: TypedElement [0..*]
specifies elements which map the semantics of the interrupt mask.

- routineConnect: BehavioralFeature [0..*]
services which connect the routine to the interrupt vector.
- \ddot{I} routineDisConnect: BehavioralFeature [0..*]
identifies services which disconnect the routine to the interrupt vector.
- \ddot{I} vectorElements: TypedElement [0..*]
specifies elements which map the semantics of the interrupt vector.

Constraints

- None

Notations

The image associated with that stereotype is:

Figure 14.31 - The interrupt notation

InterruptKind (from MARTE::SRM::SW_Concurrency)

The InterruptKind enumerates different kind of interrupt.

Description

- HardwareInterrupt
The interrupt source is an hardware one.
- ProcessorDetectedException
Software interrupts produced by the CPU control unit while it detects an anomalous condition in executing an instruction. Some examples of "Processor-detected" exceptions are faults (divide error, device not ready) and aborts (double fault).
- ProgrammedException
Software interrupts produced by an explicit request of the programmer. Some examples of "ProgrammedException" exceptions are traps (breakpoints, debug).
- Undef Undefined mechanism.
- Other: Others mechanisms.

MemoryBroker (from MARTE::SRM::SW_Brokering)

This stereotype matches to the domain concept MemoryBroker (section F.8.8) denoted in Annex F.

MemoryBroker resources provide primarily services to manage the memory allocation, the memory protection and the memory access.

Extensions

- None

Generalizations

- SwResource (from SW_ResourceCore) on page 196

Associations

- None

Attributes

- accessPolicy : AccessPolicyKind [0..1]
defines the access policy to the memory (read, write ...).
- memories: TypedElement [0..*]
specifies the hardware device type brokered by the driver.
- memoryBlockAddressElements: TypedElement [0..*]
specifies elements which maps the semantic of the memory block address.
- memoryBlockSizeElements: TypedElement [0..*]
specifies elements which maps the semantic of the memory block size.
- lockServices: BehavioralFeature [0..*]
services which lock the paging or the swapping.
- mapServices: BehavioralFeature [0..*]
services which map real memory onto the virtual address ranges used in memory partition.
- unlockServices: BehavioralFeature [0..*]
services which unlock the paging or the swapping.
- unMapServices: BehavioralFeature [0..*]
services which unmap real memory onto the virtual address ranges used in memory partition.

Constraints

[1] Types of memories values must be stereotyped either as "StorageResource" or as "StorageResource" sub-Stereotype.

Notations

The image associated with that stereotype is:

Figure 14.32 - The memoryBroker notation

MemoryPartition (from MARTE::SRM::SW_Concurrency)

This stereotype matches to the domain concept MemoryPartition (section F.8.9) denoted in Annex F.

MemoryPartition represents a virtual address space and insures that each concurrent resource associated to a specific memory partition can only access and change its own memory space.

Extensions

- NameSpace (from UML::Kernel::Classes)

Generalizations

- SwResource (from SRM::SW_ResourceCore) on page 196

Associations

- None

Attributes

- concurrentResources: TypedElement [0..*]
specifies concurrent resource executing in that address space.
- exitServices: BehavioralFeature [0..*]
release an address space.
- forkServices: BehavioralFeature [0..*]
spawn a new address space.
- memorySpaces: TypedElement [0..*]
specifies parts of the memory linked to this address space.

Constraints

- [1] Types of concurrentResources values must be stereotyped either as "SwConcurrentResource" or as "SwConcurrentResource" sub-Stereotype.
- [2] Types of memorySpaces values must be stereotyped either as "StorageResource" or as "StorageResource" sub-Stereotype.

Notations

The image linked to that stereotype is:

Figure 14.33 - The memoryPartition notation

MessageComResource (from MARTE::SRM::SW_Interaction)

This stereotype matches to the domain concept MessageComResource (section F.8.10) denoted in Annex F.

MessageComResource defines communication resource to exchange message

Extensions

- None

Generalizations

- SwCommunicationResource (from SRM ::SW_Interaction) on page 193

Associations

- None

Attributes

- isFixedMessageSize : Boolean
specifies whether all messages managed by the resource have the same size.
- mechanism: MessageResourceKind [0..1]
specifies the kind of mechanism use to exchange message
- messageQueueCapacityElements: TypedElement [0..1]
specifies the upper limit of message number allowed in a queue.
- messageQueuePolicy: QueuePolicyKind [0..1]
defines the algorithm to manage the outgoing message queue.
- messageSizeElements : TypedElement [0..*]
specifies the parameter used in message exchange services to define the size of the message.
- receiveServices : BehavioralFeature [0..*]
identifies services which get a message.
- sendServices : BehavioralFeature [0..*]
identifies services which set a message.

Constraints

- None

Notations

The image associated with that stereotype is:

Figure 14.34 - The MessageComResource notation

MessageResourceKind (from MARTE::SRM::SW_Interaction)

The MessageResourceKind enumerates common mechanisms provide by platform to exchange data.

Literals

- Blackboard Defines a one message buffer.
- MessageQueue Defines a multiple message buffer.
- Pipe Defines POSIX Pipe mechanism, which allows data flow among separate memory partition.
- Undef Undefined mechanism.
- Other Other mechanisms.

MutualExclusionResourceKind (from SW_Interaction)

The MutualExclusionResourceKind enumerates common mechanisms provide by platform to synchronize resource.

Literals

- BooleanSemaphore defines a binary semaphore. It is a flag available or unavailable. There is no proprietary purpose. Anybody can give the semaphore even if it does not take it.
- CountSemaphore defines a counting semaphore for which every time the semaphore is given the count is incremented; every time the semaphore is given the count is decremented.
- Mutex defines a binary semaphore associated with a propriety concept, resource can give the semaphore if and only if the resource takes it.
- Undef undefined mechanisms.
- Other other mechanisms.

NotificationKind (from MARTE::SRM::SW_Interaction)

The NotificationKind enumerates common policy to access a resource.

Literals

- Bounded each occurrence increments a counter.
- Memorized occurrences are memorized in a buffer.
- Memoryless occurrences are not memorized in a buffer, hence multiple occurrences are lost.
- Undef undefined.
- Other user's specific policy.

NotificationResourceKind (from MARTE::SRM::SW_Interaction)

The NotificationResourceKind enumerates common mechanisms provide by support to notify occurrence.

Literals

- Barrier barrier mechanism.

- Event event mechanism.
- Undef undefined mechanisms.
- Other other mechanisms.

NotificationResource (from MARTE::SRM::SW_Interaction)

This stereotype matches to the domain concept NotificationResource (section F.8.15 page 505) denoted in Annex F.

NotificationResource supports control flow by notifying the occurrences of conditions to awaiting concurrent resources.

Extensions

- None

Generalizations

- SwSynchronizationResource on page 198

Associations

- None

Attributes

- clearServices: BehavioralFeature [0..*]
services which erase one or several occurrences.
- flushServices: BehavioralFeature [0..*]
services to release any resource which wait for an occurrence.
- maskElements: TypedElement [0..*]
elements which map the semantic of the mechanism to mask occurrence.
- mechanism : NotificationResourceKind
identifies notification mechanism.
- occurrenceCountElements: TypedElement [0..*]
elements which map the semantic of the occurrence number.
- occurrenceKind : NotificationKind
specifies the kind of notification.
- signalServices: BehavioralFeature [0..*]
services which send one or several occurrences.
- waitServices: BehavioralFeature [0..*]
services to wait one or several occurrences.

Constraints

- None

Notations

The image associated with that stereotype is:

Figure 14.35 - The NotificationSynchronization notation

QueuePolicyKind (from MARTE::SRM::SW_Interaction)

The QueuePolicyKind enumerates algorithms provide by resources to order a queue.

Literals

- FIFO the first element put in the queue is the first outgoing.
- LIFO the last element put in the queue is the first outgoing.
- Priority each element is annotated with a priority.
- Undef undefined.
- Other other algorithms.

SharedDataComResource (from MARTE::SRM::SW_Interaction)

This stereotype matches to the domain concept SharedDataComResource (section F.8.17) denoted in Annex F.

SharedDataComResource define specific resource used to share the same area of memory among concurrent resources.

Extensions

- None

Generalizations

- SwCommunicationResource (from SRM:SW_Interaction) on page 193

Associations

- None

Attributes

- readServices: BehavioralFeature [0..*]services which read the shared data.
- writeServices: BehavioralFeature [0..*]services which write the shared data.

Constraints

- None

Notations

The image associated with that stereotype is:

Figure 14.36 - The SharedDataComResource notation

SwAccessService (from MARTE::SRM::SW_ResourceCore)

This stereotype matches to the domain concept SwAccessService (section F.8.18) denoted in Annex F.

The services provided by a software resource to access its characteristics: the accessor and the setter.

Extensions

- None

Generalizations

- GrService (from GRM)

Associations

- None

Attributes

- accessedElement: Property [1] the property which is accessed by this service.
- isModifier: Boolean specifies if the access modify the resource feature pass by parameters of this service.

Constraints

- None.

SwCommunicationResource (abstract) (from MARTE::SRM::SW_Interaction)

This abstract stereotype matches to the domain concept SwCommunicationResource (section F.8.19) denoted in Annex F.

SwCommunicationResource defines data exchange interaction among concurrent resources.

Extensions

- None.

Generalizations

- SwInteractionResource (from SRM ::SW_Interaction) on page 195.
- CommunicationMedia (from GRM) on page 102.

Associations

- None.

Attributes

- None

Constraints

- None

SwConcurrentResource (abstract) (from MARTE::SRM::SW_Concurrency)

This abstract stereotype matches to the domain concept SwConcurrentResource (section F.8.20) denoted in Annex F.

This resource defines entities which may execute concurrently sequential part of instructions.

Extensions

- None

Generalizations

- SwResource (from SRM::SW_ResourceCore) on page 196

Associations

- None

Attributes

- activateServices: BehavioralFeature [0..*]
services which make available a resource to execute. As result, activated resource are ready to compete for the computing resource. In case of interruption, it results in explicitly raised the interrupt (i.e to set of the interrupt).
- activationCapacity: Integer [0..1]
specifies the activation number allowed in the system.
- addressSpace: TypedElement [0..1]
defines the address space in which the flow is executed.
- disableConcurrencyServices : BehavioralFeature [0..*]
services which lock the competition for a computing resource. As result, any concurrent resource cannot pre-empt the executing resource.
- enableConcurrencyServices: BehavioralFeature [0..*]
services which unlock the competition for a computing resource. As result, any concurrent resource can pre-empt the executing resource.
- entryPoints: Elements [0..*]
defines entry points of the resource.
- heapSizeElements : TypedElement [0..*]
elements which maps the semantic of the resource heap size in case of dynamic memory allocation.
- periodElements: TypedElement [0..*]
elements which maps the semantic of the resource period in case of a periodic concurrent resource.
- priorityElements: TypedElement [0..*]

elements which maps the semantic of the resource priority.

-
- `stackSizeElements`: `TypedElement [0..*]`
elements which maps the semantic of the resource stack size.
- `type` : `ArrivalPattern` (from `MARTE_Library::BasicNFP_Types::ArrivalPattern`)
identifies the occurrence execution pattern.
- `resumeServices`: `BehavioralFeature [0..*]`
services which make available a resource to compete with either ready or pending concurrent resource. Pending resources are blocked due to the unavailability of some other resources. In case of interrupt, resume service is equivalent to an enable service.
- `suspendServices`: `BehavioralFeature [0..*]`
services which make unavailable a resource to execute. In case of interrupt, suspend service is equivalent to disable service.
- `terminateServices`: `BehavioralFeature [0..*]`
services which stop definitively resource execution.
- `sharedDataResources`: `TypedElement [0..*]`
resources use to share data among computing resources. Those resource types must be stereotyped as `"SRM::SW_Interaction::SharedDataComResource"`.
- `messageResources`: `TypedElement [0..*]`
resources use to communicate messages among computing resources. Those resource types must be stereotyped as `"SRM::SW_Interaction::MessageComResource"`.
- `mutualExclusionResources`: `TypedElement [0..*]`
resources use to synchronize mutual accesses. Those resource types must be stereotyped as `"SRM::SW_Interaction::SwMutualExclusionResource"`.
- `notificationResources`: `TypedElement [0..*]`
defines resources use to synchronize computing resources. Those resource types must be stereotyped as `"SRM::SW_Interaction::NotificationResource"`.

Constraints

- [1] Type of the `addressSpace` value must be stereotyped as `"MemoryPartition"`.
- [2] `entryPoints` values must be stereotyped as `"EntryPoint"`.
- [3] `sharedDataResources` values must be stereotyped as `"SRM::SW_Interaction::SharedDataComResource"`.
- [4] `messageResources` values must be stereotyped as `"SRM::SW_Interaction::SwMutualExclusionResource"`.
- [5] `mutualExclusionResources` values must be stereotyped as `"SRM::SW_Interaction::SwMutualExclusionResource"`.
- [6] `notificationResources` values must be stereotyped as `"SRM::SW_Interaction::NotificationResource"`.

SwInteractionResource (abstract) (from MARTE::SRM::SW_Interaction)

This stereotype matches to the domain concept `SwInteractionResource` (section F.8.21) denoted in Annex F.

InteractionResource is an abstract concept which denotes generic mechanism to interact among concurrent executing resources. Synchronization and Communication are specific kind of interaction.

Extensions

- None

Generalizations

- SwResource (from SRM::SW_ResourceCore) on page 196

Associations

- None

Attributes

- isIntraMemoryPartitionInteraction: Boolean [0..1]
specifies if the mechanism can be accessed from different memory partition (i.e namespace, address space).
- waitingPolicyElements: TypedElement [0..*]
elements by which the communication waiting policy is specified: waiting, ready, waiting with a time out, conditional waiting...
- waitingQueuePolicy: QueuePolicyKind [0..*]
defines the algorithm to manage the resource waiting queue.
- waitingQueueCapacity: Integer [0..1]
the number of resources allowed in the waiting queue.

Constraints

- None

SwMutualExclusionResource (from MARTE::SRM::SW_Interaction)

This stereotype matches to the domain concept SwMutualExclusionResource (section F.8.22) denoted in Annex F.

MutualExclusionResource describe resources commonly used for synchronize access to shared variables.

Extensions

- None

Generalizations

- SwSynchronizationResource on page 198

Associations

- None

Attributes

- accessTokenElements : TypedElement [0..*]

elements which maps the semantics of the token used to access a shared information.

- `acquireServices`: BehavioralFeature [0..*]
services which get an access token to a shared information.
- `concurrentAccessProtocol` : ConcurrentAccessProtocolKind
specifies the protocol applied in concurrent access.
- `mechanism` : MutualExclusionResourceKind
specifies the kind of mechanism use to mutual exclusion synchronization.
- `releaseServices`: BehavioralFeature [0..*]
services which release an access token to a shared information.

Constraints

- None

Notations

The image associated with that stereotype is:

Figure 14.37 - The SwMutualExclusionResource notation

SwResource (abstract) (from MARTE::SRM::SW_ResourceCore)

This stereotype matches to the domain concept SwResource (section F.8.23) denoted in Annex F.

SwResource model software structural entities provided to the user by execution supports.

Extensions

- None

Generalizations

- Resource (from GRM on page 117)

Associations

- None

Attributes

- `createServices`: BehavioralFeature [0..*]
services which allocate and declare the resource to the system.
- `deleteServices`: BehavioralFeature [0..*]
services which free and delete the resource from the system.

- identifierElements: TypedElement [0..*]
elements which map the semantic of a resource identifier.
- initializeServices: BehavioralFeature [0..*]
services which initialize the resource.
- memorySizeFootprintElements: TypedElement [0..1]
elements which map the memory size footprint of the resource.
- stateElements: TypedElement [0..*]
elements which map the semantic of the resource state.

Constraints

- None

SwSchedulableResource (from MARTE::SRM::SW_Concurrency)

This stereotype matches to the domain concept SwSchedulableResource (section F.8.24) denoted in Annex F. SchedulableResource are resources which executes concurrently to other concurrent resource.

Extensions

- None

Generalizations

- SwConcurrentResource (from SRM::SW_Concurrency) on page 193

Associations

- None

Attributes

- deadlineElements: TypedElement [0..*]
elements which maps the semantic of the deadline feature.
- deadlineTypeElements : TypedElement [0..*]
elements which map the semantic of the deadline criticality degree (e.g., soft and hard).
- delayServices: BehavioralFeature [0..*]
services which delay for a lapse of time the execution. The resource is in a dormant state during this lapse.
- isPreemptable: Boolean [0..1]
specifies if the scheduler can pre-empt that kind of resource.
- isStaticSchedulingFeature: Boolean [0..1]
specifies if the scheduling parameters (priority, deadline, timeslice ...) are static (i.e., constants define off-line).
- joinServices: BehavioralFeature [0..*]
services which suspend the execution of set of concurrent resource until other concurrent resources terminates.

- scheduler: TypedElement [1]
Specifies the scheduler which orchestrate the concurrent execution of this kind of resource.
- timeSliceElements: TypedElement [0..*]
elements which maps the semantic of the timeSlice in case of round robin scheduling
- yieldServices: BehavioralFeature [0..*]
services which explicitly relinquish the computing resource. They explicitly ask scheduler to reschedule.

Constraints

[1] The type of scheduler value must be stereotyped either as "Scheduler" or as "Scheduler" sub-Stereotype.

Notations

The image associated with that stereotype is:

Figure 14.38 - The SwSchedulableResource notation

SwSynchronizationResource (abstract) (from MARTE::SRM::SW_Interaction)

This stereotype matches to the domain concept SwSynchronizationResource (section F.8.25) denoted in Annex F.

This resource defines interaction mechanisms to synchronize concurrent execution flow.

Extensions

- None

Generalizations

- SwInteractionResource (from SRM::SW_Interaction) on page 195.
- SynchronizationResource (from GRM) on page 102.

Associations

- None

Attributes

- None

Constraints

- None

SwTimerResource (from MARTE::SRM::SW_Concurrency)

This stereotype matches to the domain concept SwTimerResource (section F.8.26) denoted in Annex F.

A SwTimerResource represents an entity that is capable of following and evidencing the pace of time upon demand with a prefixed maximum resolution, at programmable time intervals.

Extensions

- None

Generalizations

- TimerResource (from GRM::ResourceTypes) on page 104

Associations

- None

Attributes

- DurationElements : TypedElement [0..*] {redefines GRM::TimerResource::duration}
elements which map the semantic of the interval after which the timer will make evident the elapsed time.

Constraints

- None

Notations

The image associated with that stereotype is:

Figure 14.39 - The SwTimerResource notation

14.1.4 Examples

The following examples illustrate how the SRM sub-profile stereotypes may be used in practice. Several brief case studies are described for each sub-profile. In a first section, modeling possibilities are exhaustively described. In a second section, some concrete RTOS concepts are modeling. In addition, section D.5 provides two examples of RTOS API model library, for OSEK VDX and ARINC-653, build with the SRM profile.

14.1.4.1 Modeling possibilities

The idea of this section is to describe common use of SRM sub-Profile stereotypes. It aims to give an overview of typical modeling possibilities. The list of examples is by no means exhaustive.

Applying SwResource stereotypes on classifiers

All stereotypes of the SRM sub-profile extend the UML::Classes::Kernel::Classifier metaclass. Thus, any UML Classifier sub-metaclass may be extended by those stereotypes (e.g. Class, Interface, Component and AssociationClass). Figure 14.40 and Figure 14.41 illustrate UML Class and UML Component extension.

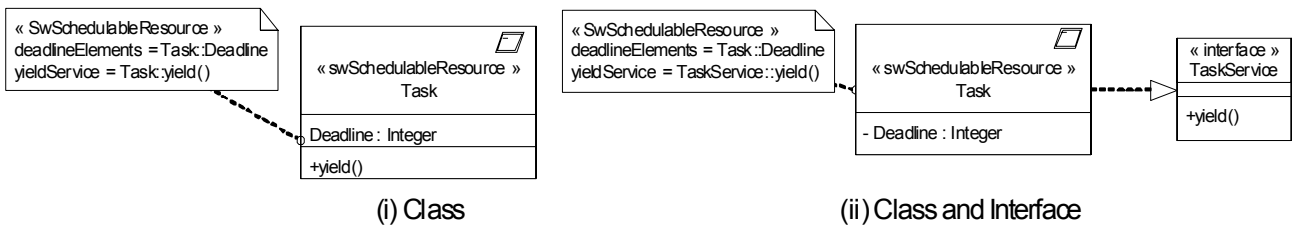

Figure 14.40 - Class extension example

Figure 14.41 - Component extension example

Figure 14.42 illustrates the use of an AssociationClass (from UML::CompositesStructures::InternalStructures) to describe interaction between concurrent computing resources. As the SwInteractionResource stereotype extends the UML Classifier metaclass, an UML AssociationClass may be stereotyped as any SwInteractionResource sub-stereotype (for example: NotificationResource, MessageComResource, SwMutualExclusionResource ...). In this example, the execution support provides concurrent resource to compute instructions: "Alarm" and "Task". They are described as UML classes and respectively stereotyped as "Alarm" and as "SwSchedulableResource". In this example, an "Alarm" resource may interact with a "SwSchedulableResource" (i.e. a task) by mean of an event mechanism stereotyped "NotificationResource".

Figure 14.42 - AssociationClass extension example

Applying SwResource stereotypes on properties

All stereotypes of the SRM sub-profile extend the UML::ConnectableElement meta class (from UML::CompositeStructures::InternalStructures). Figure 14.43 illustrates the use of such extension to describe interactions between concurrent computing resources in a memory partition.

Figure 14.43 - ConnectableElement extension example

Applying the EntryPoint stereotype on dependencies

Figure 14.44 denotes a use of the entryPoint stereotype on an UML::Dependency. This example illustrates a robotic application build upon a generic API. This design is a part of a robot controller in charge of the motion control. On the left side, the software designer describes the logical "RobotController" model. On the right side, the SRM profile is used to describe the MemoryPartiton and the SchedulableResource provided by a generic real-time and embedded API. Then, a model is described as instances of the MemoryPartition and Schedulable resources. Hence, the Task instances are bound with their entryPoint by means of UML 2.0 dependency. In case of the "t2" instanceSpecification, the stereotype "entryPoint" is used to specify that the "trajectoryControl" operation of a specific MotionController instanceSpecification is the routine which has to be executed in the context of that schedulable resource.

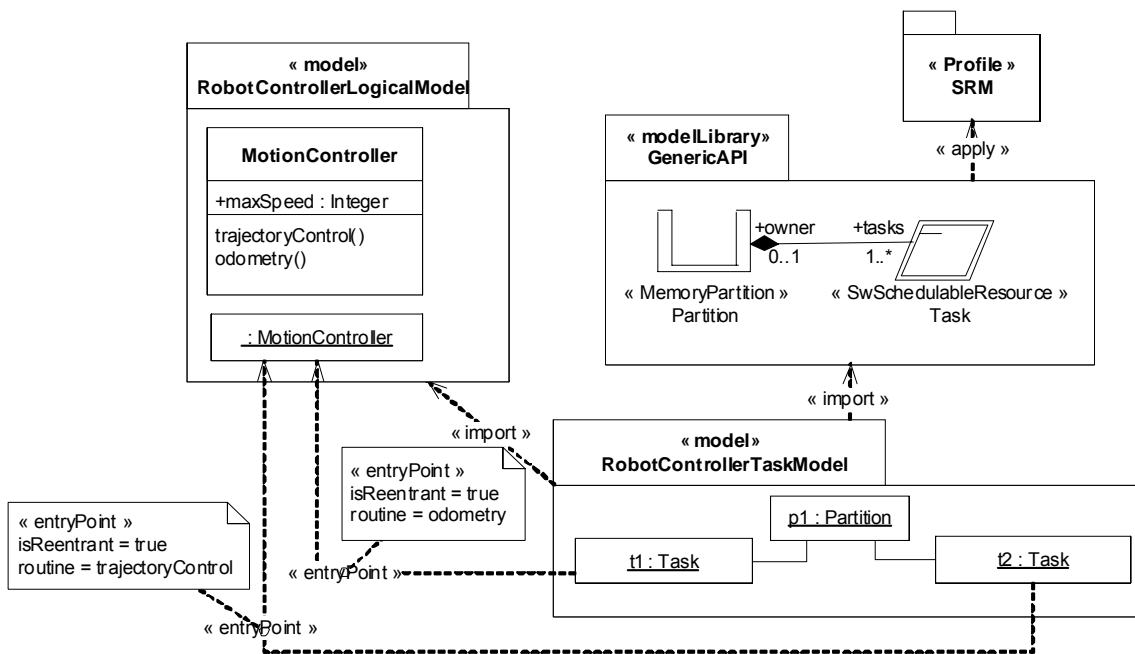

Figure 14.44 - EntryPoints examples

Applying the SwAccessService stereotype on services

"Get" and "Set" services may be formally clarify with the SwAccessService stereotype. In the example depicted in Figure 14.45, the "sem_getValue" service returns the semaphore value. Hence, it is stereotyped as "SwAccessService". The tag "accessedElement" specifies that the feature accessed is the property named "value". Therefore, the boolean tag "isModifier" indicates that this service does not modify the value.

Figure 14.45 - SwAccessService example

Tagged values examples

Stereotype properties allow users to precise semantics of elements. For example in Figure 14.40, the "Deadline" property is tagged to clarify its semantic. It denotes explicitly in the model that among all attributes of this class, one refers to the task deadline. That is named "Deadline". Thus, it allows tools to distinguish properties and to permit automatic model transformations (code generation for example).

In the second part of the Figure 14.40, the "TaskService" interface owns a "yield" operation. This operation is tagged as a "yieldServices" by the "SwSchedulableResource" stereotype, whereas this stereotype is not applied to the interface. It means that in the context of a "task", the service to call in order to release the computing resource is the operation "yield" of the interface "TaskService".

Multiple tagged values for the same tag and multiple tags for the same feature are allowed. On the one hand user can express formally multiple semantics for the same feature through multiple tags. On the other hand, user can express the same semantic for multiple features through the same tag. Figure 14.46 describes a "taskSpawn()" service as both task creating and task activating. In the same way, to activate a task, you can either call the "taskSpawn()" service or the "taskActivate()" one. Figure 14.47 illustrates that user may reference UML properties as well as UML parameters to the same tag.

Figure 14.46 - Multiple tags and multiple tagged services

Figure 14.47 - Multiple tagged features

14.1.4.2 Specific RTOS API examples

The idea of this section is to describe concrete use of SRM sub-Profile stereotypes. Those stereotypes are applied to specific RTOS concepts. Some explanations are given for each case study. In addition, large examples of specific UML model libraries using the SRM profile are described in the section D.4. Thus, some parts of OSEK/VDX (OS 2.2.2) and ARINC (653-1) APIs are described as examples.

SwSchedulableResource and MemoryPartition example

To illustrate the use of the "SwSchedulableResource" and "MemoryPartition" stereotypes, the Figure 14.48 is aiming to represent the POSIX Process and Pthread concepts modeled as UML classes. POSIX process is an address space with one or more threads executing within that address space, and the required system resources for those threads. Each process shall be controlled by a priority. Hence, POSIX Process is conforms to both a "MemoryPartition" and a "SwSchedulableResource". The PID attribute is the process identifier. Hence, this attribute is assigned to the "identifierElements" inherited tagged value of the "SwResource" stereotype. That tagged value clarifies the semantic of the PID attribute. It explains explicitly in the model that the attribute named "PID" refers to the process identifier. POSIX thread (i.e, pthread) is a single flow of control within a process. Anything whose address may be determined by a thread is accessible to all threads in the same process. Each thread shall be controlled by an associated priority. Hence, a POSIX Thread is a conformed to a "SwSchedulableResource" and associated with the "Process" classifier.

Figure 14.48 - POSIX Process and Pthread example

InterruptResource example

Figure 14.49 illustrates the OSEK/VDX interrupt resource modeled as an UML class. OSEK interrupts are scheduled by hardware while tasks (i.e., OSEK schedulableResource) are scheduled by the scheduler. Interrupts can interrupt tasks (preemptable and non preemptable tasks). OSEK offers fast functions to suspend (i.e., disable) and resume (i.e., enable) interrupts.

Figure 14.49 - OSEK/VDX Interrupt example

Alarm example

Figure 14.50 illustrates the use of the "Alarm" stereotype. The OSEK operating system provides services for processing recurring events. Such events may be for example timers that provide an interrupt at regular intervals, or encoders at axles that generate an interrupt in case of a constant change of a (camshaft or crankshaft) angle, or other regular application specific triggers. The OSEK operating system provides a two-stage concept to process such events. The recurring events (sources) are registered by implementation specific counters. Based on counters, the OSEK operating system software offers alarm mechanisms to the application software, such as services to activate tasks, set events or call an alarm-callback routine (i.e., the alarm entry point) when an alarm expires. Note that the SwTimerResource is directly used to stereotype OSEK/VDX Counter.

Figure 14.50 - OSEK/VDX Alarm example

SwMutualExclusionResource example

Figure 14.51 illustrates one use of the "SwMutualExclusionResource" stereotype to clarify the semantic of the POSIX semaphore type, named Sem_t. POSIX semaphore may be used to guard access to any resource accessible by more than one schedulable resource in the system. A concurrent resource that wants access to a critical resource (section) has to wait for (i.e., to acquire) the semaphore that guards that resource. When the semaphore is locked on behalf of a concurrent resource, it knows that it can use the resource without interference by any other cooperating concurrent resource in the system. When the concurrent resource finishes its operation on the critical resource, leaving it in a well-defined state, it releases the semaphore, indicating that some other concurrent resource may now obtain the resource protected by that semaphore.

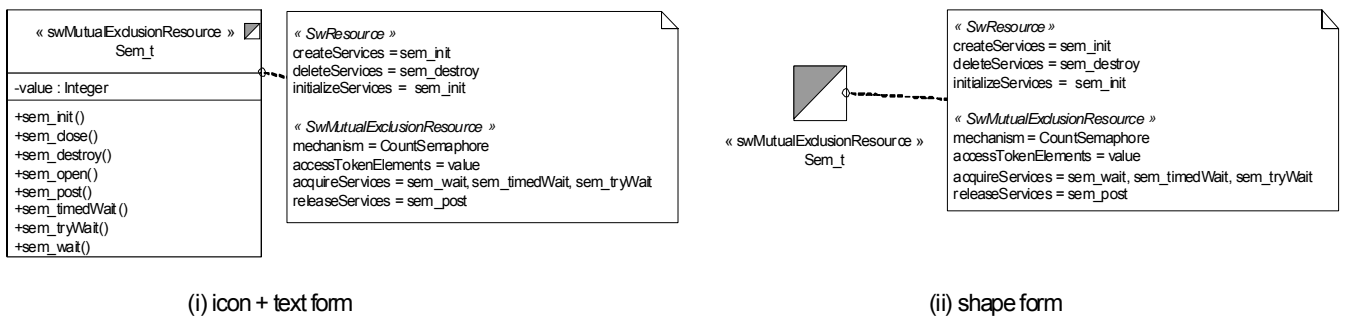

Figure 14.51 - POSIX semaphore example

MessageComResource example

Figure 14.52 shows a representation of the ARINC-653 Buffer and Event mechanism. ARINC-653 Buffer is stereotyped MessageComResource. That mechanism is a communication object used by schedulable resources (i.e., ARINC-653 process) of a same memory partition (i.e., ARINC-653 partition) to send or receive message.

ARINC-653 Event is a communication object used to notify of a condition to schedulable resources (i.e., ARINC-653 processes) which may wait for it. Hence, it is stereotyped "NotificationResource".

Figure 14.52 - ARINC-653 Event and Buffer example

14.2 Hardware Resource Modeling (HRM)

14.2.1 Overview

This chapter provides mechanisms to model the hardware (HW) part of embedded systems, which is essential to fulfill the application specification. When interfacing hardware and software design flows, it is a common practice to specify abstracted and understandable models in order to communicate design intends and to study interdependencies affecting design decisions. At the end, the hardware modeled resources are combined with the software (SW) ones to support the whole application execution.

Hardware is extraordinary various, several architectures and a huge amount of hardware components exist. It is also continuously varying with many new emerging technologies. Therefore, modeling such a domain requires a highly expressive language. The UML mechanisms like generalization, composition, encapsulation, separation of concerns

(structure/behavior), abstraction (different views), and refinement, are well adapted for that dilemma. The Deployments package of UML specifies constructs like DeploymentTarget, Node, or Device, which can be used to define roughly a hardware architecture that is to serve as the target of software artifacts. Our scope is larger, we aim to cover many aspects:

- Software design and allocation using a high level hardware description model of the targeted hardware architecture, with some details about available resources, instruction set family, memory size. Such model is a formal alternative to block diagrams.
- Analysis and simulation of a specialized hardware description model:
 - The nature of details depends on the analysis focus and the simulated resources. For example, schedulability analysis requires details on the processor throughput, memory organization and communication bandwidth, whereas power analysis will focus on power consumption, heat dissipation and the layout of the hardware components.
 - The required level of detail depends on the analysis and simulation accuracy. The performance simulation needs a fine description of the processor microarchitecture and memory timings, whereas many functional simulators simply require entering the instruction set family.
- Hardware constructors can describe their products with a kind of model-based datasheets. They must provide a detailed hardware design model refined with specific details.

In order to support all use cases enumerated above, we extend UML using a profile based on a detailed Hardware Resource Model. This latter is intended to serve for description of existing and conception of new hardware platforms, through different views and detail levels. In a few words, the Hardware Resource Model is grouping most hardware concepts under a hierarchical taxonomy with several categories depending on their nature, functionality, technology and form.

Separation of concerns and abstraction are the main qualities of this profile. It eases adaptation to many orthogonal activities. The Hardware Resource Model is composed of two views, a logical view that classifies hardware resources depending on their functional properties, and a physical view that concentrates on their physical properties. Both are specializations of the general model. The logical and physical views are complementary. They provide two different abstractions of hardware and they could be simply merged (example 14.2.4.3). In turn, each view is composed of many models differentiated by other criteria.

Stereotypes introduced within this chapter are organized under a tree of successive inheritances from generic stereotypes to specific ones, no stereotype is orphan. This is the main reason behind the ability of the hardware resource profile to cover many detail levels. Optional tagged values and the composite structure of stereotypes are strengthening this ability as well.

Another feature of the Hardware Resource Model is support of most hardware concepts thanks to a big range of stereotypes and once more its layered architecture. If no specific stereotype corresponds to a particular hardware component, a generic stereotype may match. This is also appropriate to support new hardware concepts of new nature or new technologies.

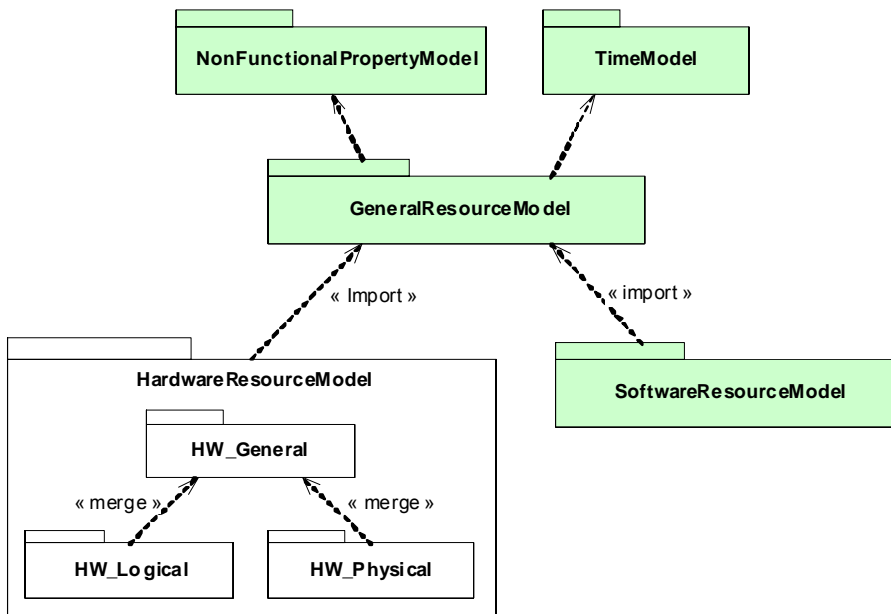

Figure 14.53 - Hardware Resource Model dependencies

Both Hardware Resource Model and Software Resource Model (SRM: chapter 14.1 on page 173) are specializations of the General Resource Model (GRM: chapter 10 on page 99). Therefore, hardware/software allocation model (Alloc: chapter 12 on page 139) benefits from the unified structure of these models.

This chapter contains all information about Hardware Resource Modeling profile. Section 2 describes the domain model, which is separated into general, logical and physical parts. In section 3, the UML representation contains the profile diagrams and the stereotype descriptions. The last section assembles illustrative examples.

14.2.2 Domain view

In this section, the hardware (HW) concepts are introduced category by category through several metamodel diagrams. Each metaclass has a detailed description in the Annex F and modeling examples are given in section 14.2.4.

In order to ease the use of the Hardware Resource Model (HRM), names of stereotypes and their attributes are rigorously chosen in accord with conventional hardware terminology. In addition, they are prefixed by the "HW_" label to save from ambiguity. e.g., HW_Timer denotes the hardware counter device and it is not a software timer.

Each metaclass attribute is chosen only if it verifies many criteria. First, it denotes a characteristic property of the metaclass that is common to all represented hardware resources. Then, it complies with the level of abstraction of the concept and the modeled view. Finally, it must be essential for at least one of the profile use cases enumerated in the introduction.

Last, many OCL rules are specified to ensure the coherency of the hardware platform model.

14.2.2.1 The Hardware General model

The HW_General model defines a typical structure of execution platforms. It is inferred from the GRM and it is a common basis for both logical and physical models.

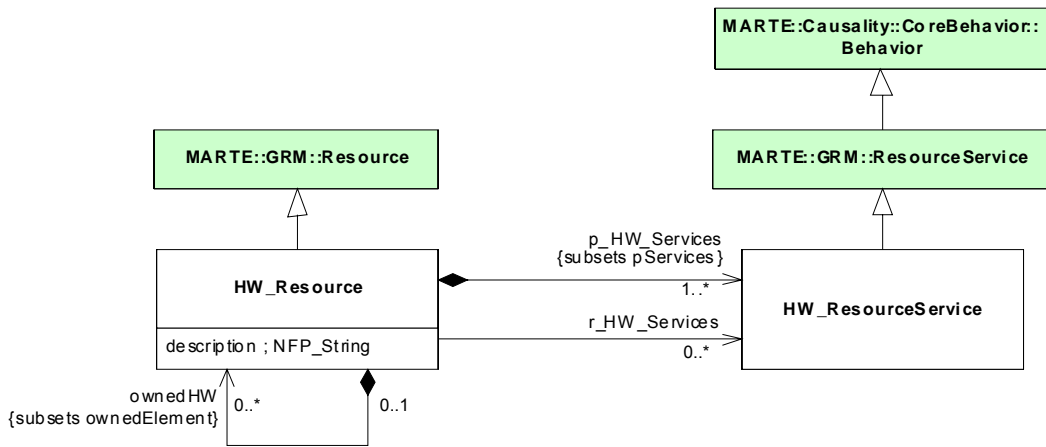

Figure 14.54 - HW_General model details

The concept of HW_Resource is generic; it denotes a generic hardware entity. It may encapsulate other owned hardware resources. This composition mechanism allows successive refinements with different granularities. From a structural point of view the HW_Resource concept is similar to UML Components but semantically an HW_Resource defines an hardware execution entity for which the services can be qualified by one or more quality-of-service characteristics.

One example of composite hardware resources is FPGA, which often contains many embedded processors, some amount of RAM and it can also be configured into many units with different functions (SMP example 14.2.4.3).

Typically, an HW_Resource provides at least one HW_ResourceService, and may require some services from other resources. Each HW_ResourceService could be detailed by many views to describe its behaviors.

Collaborations of resources by means of their services characterize the execution platform.

Most of metaclasses introduced below, are inheriting from HW_Resource and in consequence from its structure. Thus, they are associated with the HW_ResourceServices that they are offering. In order to lighten metamodels and improve their flexibility, services would not be explicitly specified if they are inherited from the GRM or intuitively deduced from the HW_Resource type (example 14.2.4.1).

14.2.2.2 The Hardware Logical model

The objective of the logical modeling is to provide a functional classification of hardware entities, whether if they are computing, storage, communication, timing or device resources. Such a classification is mainly based on services that each resource offers and optionally influenced by the resources nature (example 14.2.4.1).

The logical taxonomy is common to many previous works. It is not categorical, and the following concepts are not necessarily incompatible. One hardware resource could have many functions within the same hardware platform.

Figure 14.55 - HW_Logical model structure

HW_Logical package merges the HW_General and it is composed of five subpackages, each one for a particular resource's type. There are several dependencies between these subpackages.

HW_Computing package

The HW_Computing package defines a set of active processing resources that are central to execution platforms. HW_ComputingResources are often complex and composite; they may contain many other subresources from different HW_Logical packages (14.2.4.3).

Figure 14.56 - HW_Computing package details

HW_ComputingResource is a generic resource. It could be specialized (HW_ASIC), such resources are known to be efficient but not flexible. It could be configurable (HW_PLD), there are many technologies that have different capabilities like dynamic reconfiguration (SRAM). And it could be programmable (HW_Processor), which typically implements some instruction sets, owns caches, corresponding memory management units and adopts branch prediction policies.

HW_Storage package

The metamodel of the HW_Storage package includes two diagrams, one for the HW_Memory resource and the other for the HW_StorageManager resource.

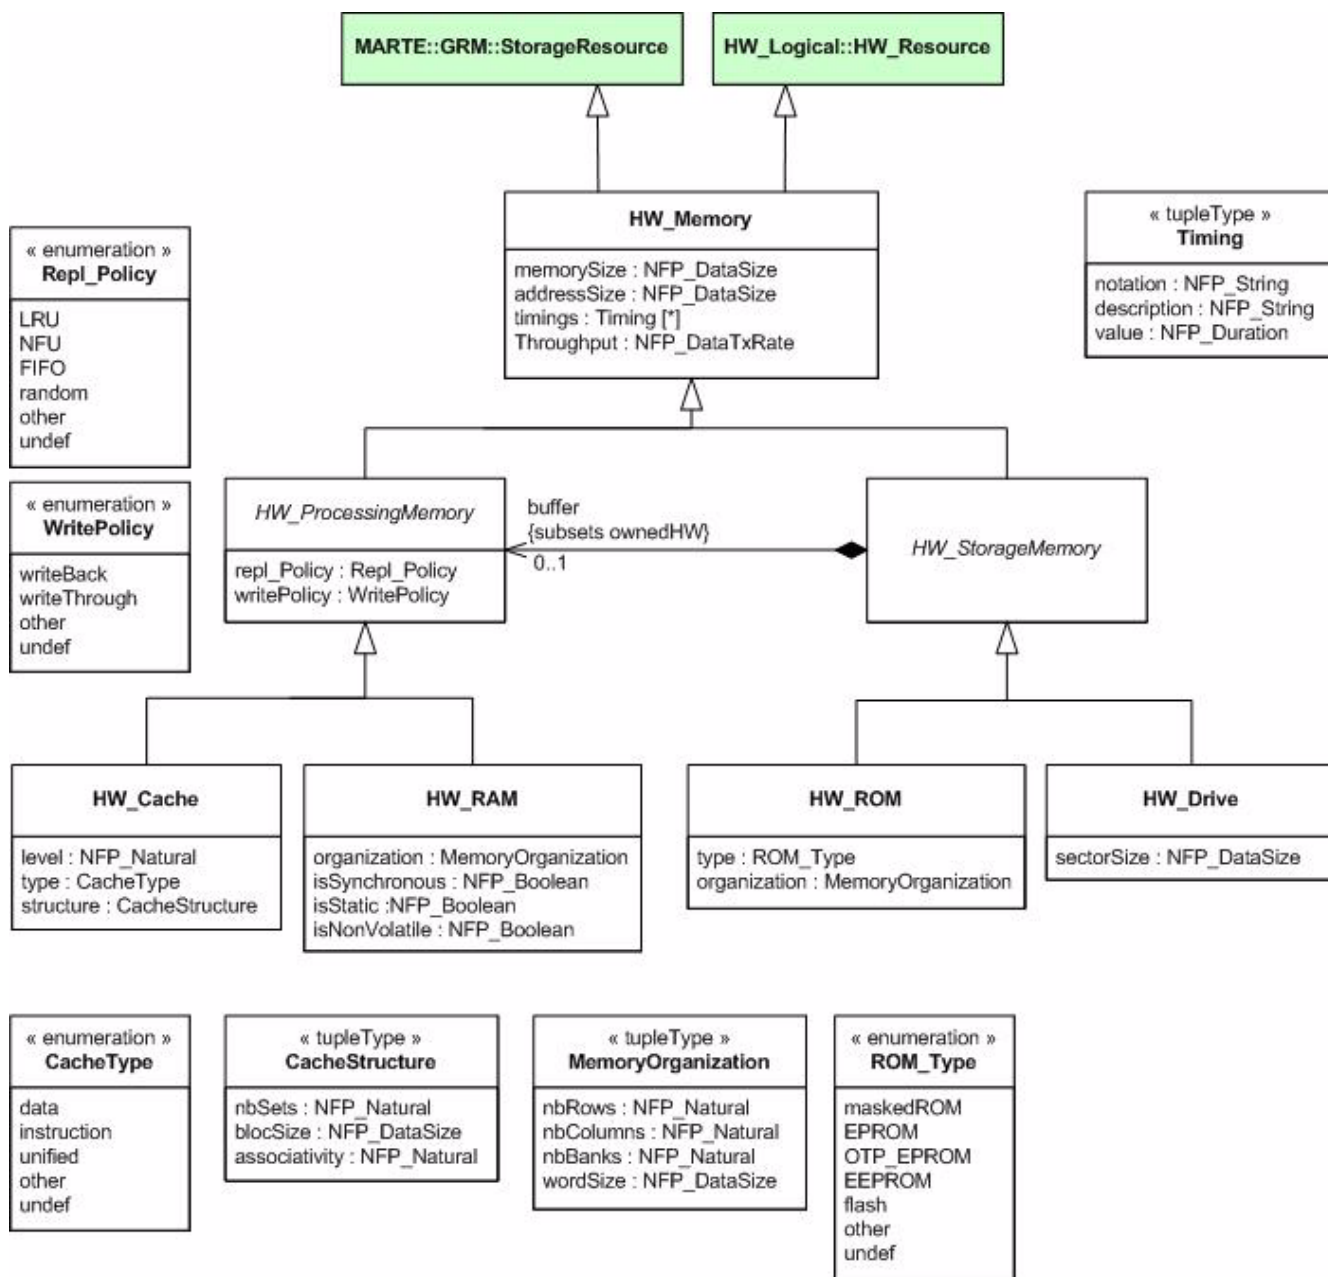

Figure 14.57 - HW_Storage package details (HW_Memory)

HW_Memory denotes a given amount of memory. It could be a HW_ProcessingMemory or HW_StorageMemory. HW_ProcessingMemory is an abstract metaclass that symbolizes a fast and volatile working memory, while HW_StorageMemory is an abstract metaclass for permanent and relatively time consuming storage devices.

In real world, RAM (Random Access Memory) take many forms, SRAM for Static RAM is often used as cache, SDRAM for Synchronous Dynamic RAM is enough fast to be used as main memory (example 14.2.4.2). But as the logical model focuses on the functionality rather than the technology, we distinguish HW_RAM for main memories and HW_Cache for cache memories.

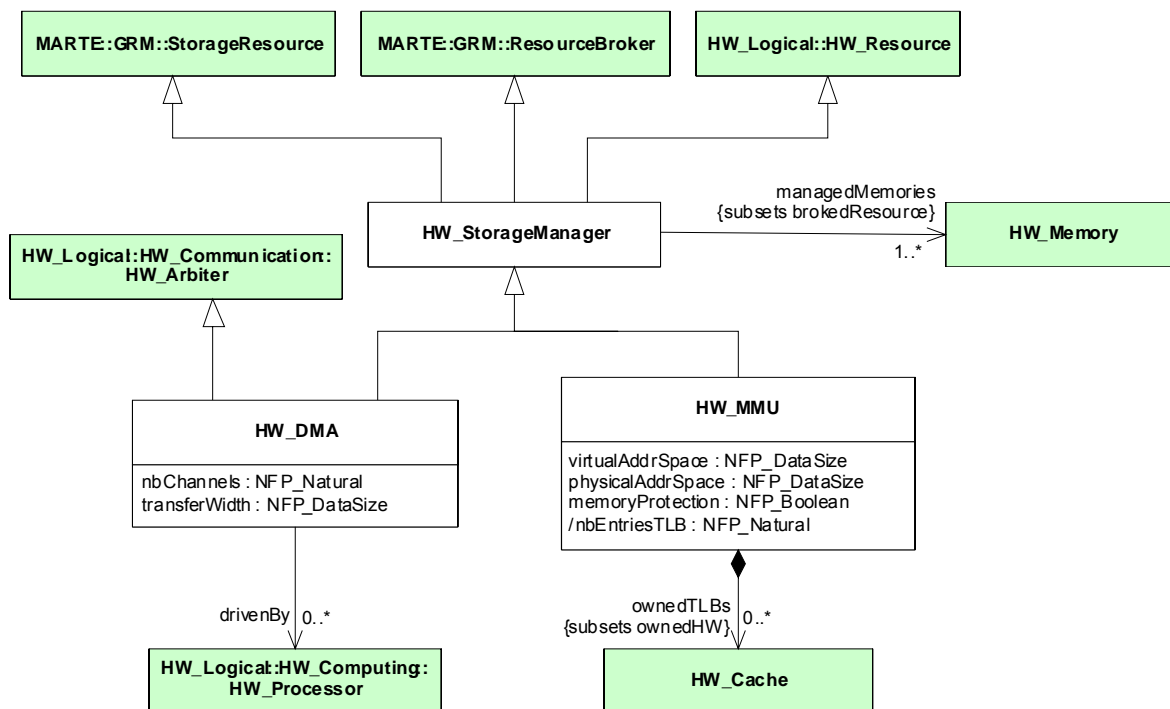

Figure 14.58 - HW_Storage package details (HW_StorageManager)

HW_StorageManager denotes memory brokers. HW_MMU for Management Memory Unit manages addresses and the content of memories. It might own TLBs (Translation Lookaside Buffer) to translate virtual into physical addresses. Whereas, HW_DMA for Direct Memory Access, combines memory management and communication control. It may be driven by an HW_Processor, and it allows devices to transfer data without subjecting the HW_Processor.

HW_Communication package

The objective of the HW_Communication package is to group all communication participants within a functional taxonomy. It offers a stand-alone communication view that supplies the skeleton of the hardware platform architecture.

Figure 14.59 - HW_Communication package details

The HW_Media is a central concept that denotes a communication resource able to transfer data with a theoretical bandwidth. It may link many HW_EndPoint(s). It could be controlled by many HW_Arbiters and it may be connected to other HW_Medias by means of HW_Bridges. An HW_EndPoint is an identified connection point of an HW_Resource (e.g. pin, port or slot).

If HW_Media is generic and symbolizes any kind of connections, HW_Bus is a particular wired channel with specific functional properties (example 14.2.4.3).

HW_Timing package

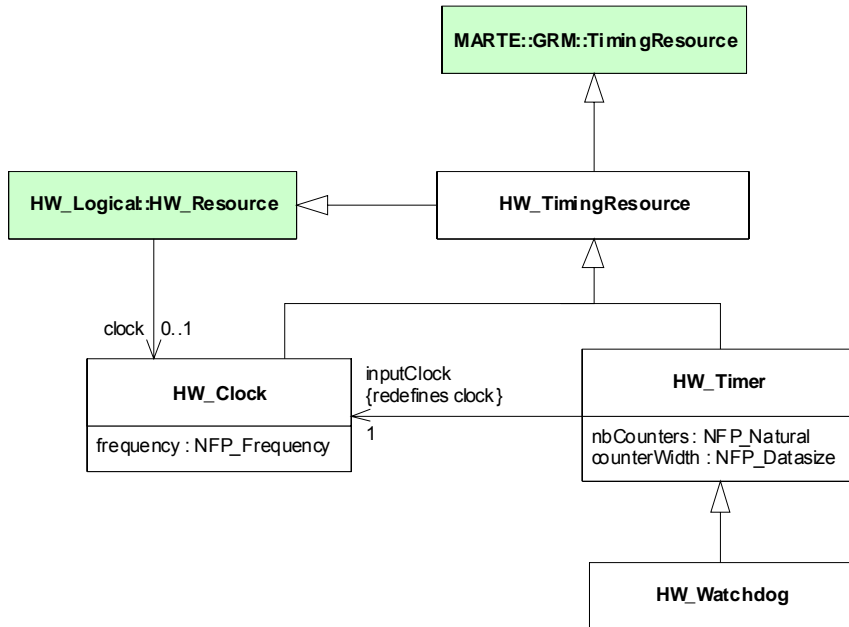

Figure 14.60 - HW_Timing package details

The Figure 14.60 defines timing resources. The **HW_Clock** is a basic periodic pulse with a definite frequency. Every **HW_Resource** can be clocked.

HW_Timer is a set of counters. The counter width determines the maximum measurement of time in terms of clock periods ($2 \times \text{counterWidth} - 1$). **HW_Watchdog** is typically a count-down timer, which sends an alarm when the zero count is reached (example 14.2.4.1).

HW_Device package

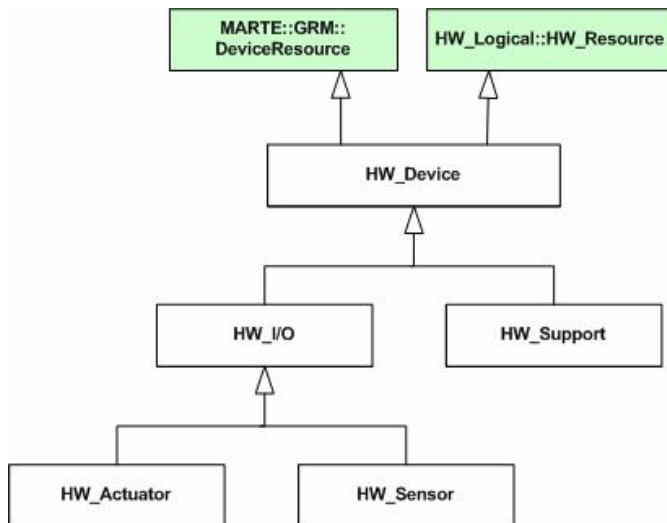

Figure 14.61 - HW_Device package details

From a functional point of view, an **HW_Device** is an auxiliary resource that is not as fundamental as computing, storage and communication resources are, but it expands the functionality of the hardware platform. It has two subcategories. The **HW_I/O** denotes resources that interact with the environment, like sensors, actuators, peripherals, displays, external port and so on. Whereas, the **HW_Support** is a support resource like power suppliers (batteries), power regulators, cooling fans, or miscellaneous electronic devices. Because of their nature, some support devices are detailed in the physical model (example 14.2.4.3).

14.2.2.3 The Hardware Physical model

The **HW_Physical** model represents hardware resources as physical components with details on their shape, size, position within platform, power consumption, heat dissipation and many other physical properties.

As most of embedded systems have limited area and weight, hard environmental conditions and a predetermined autonomy, this view helps the hardware design and mapping components on the physical platform.

Figure 14.62 - HW_Physical model structure

Same as the functional view introduced above, the HW_Physical package merges the HW_General and contains two subpackages. The HW_Layout package that focuses on the layout architecture and the HW_Power package that provides mechanisms to annotate the model with power properties.

HW_Layout package

The HW_Layout package provides mechanisms to make UML graphical diagrams as close as possible to the real hardware platform layout. It classifies hardware components depending on their forms and offers arrangement constructs using rectilinear grids (example 14.2.4.3).

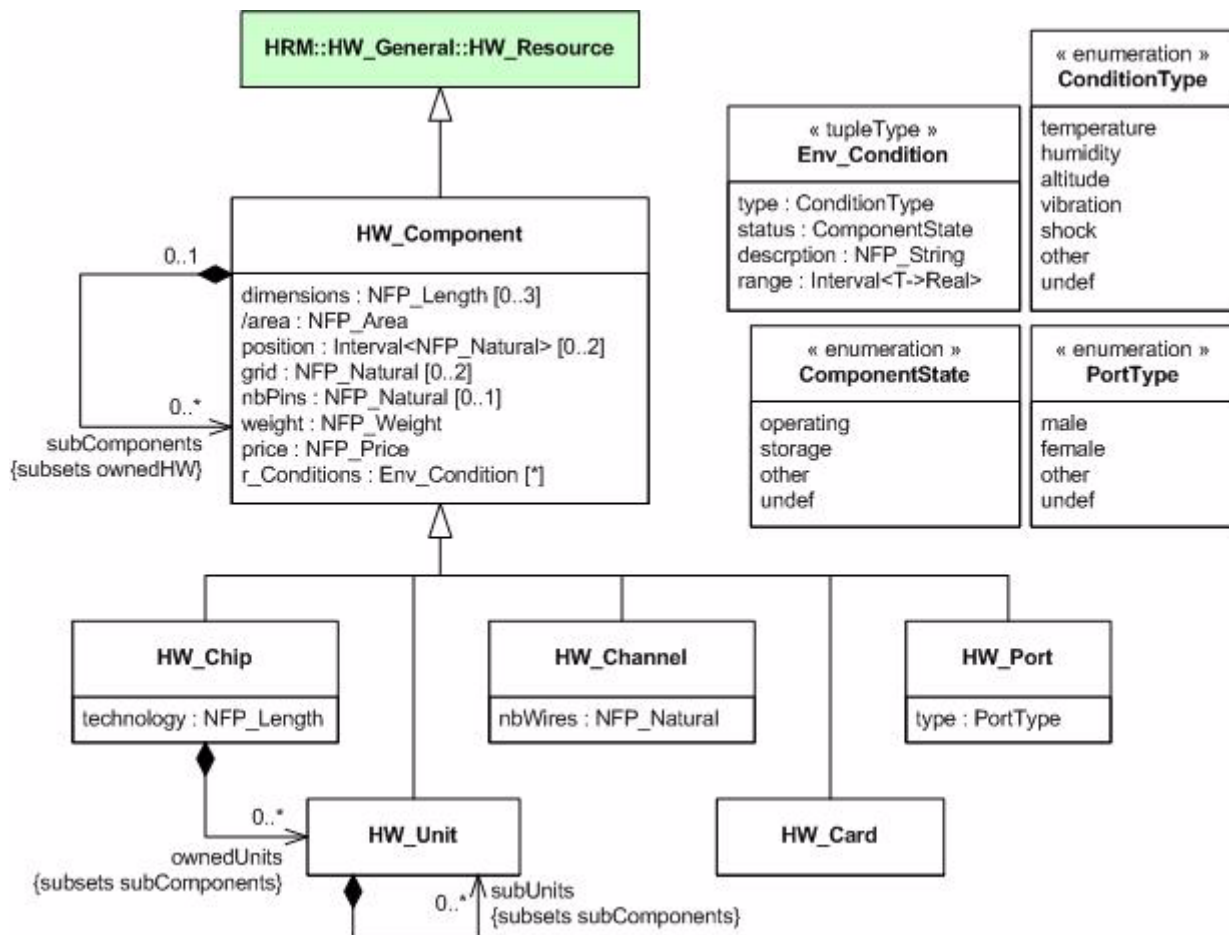

Figure 14.63 - HW_Layout package details

HW_Component denotes a generic physical component that can be refined into a grid of subcomponents. It has dimensions, a resulting area, a particular weight and optionally a number of pins and a position within a potential container. Each HW_Component requires some environmental conditions whether if it is in use or not.

HW_Power package

The HW_Power package comes with a detailed description of HW_Component power consumption and heat dissipation. It enables advanced power analysis and autonomy optimization that are crucial for embedded systems. Notice that the HW_Layout may also influence the power analysis.

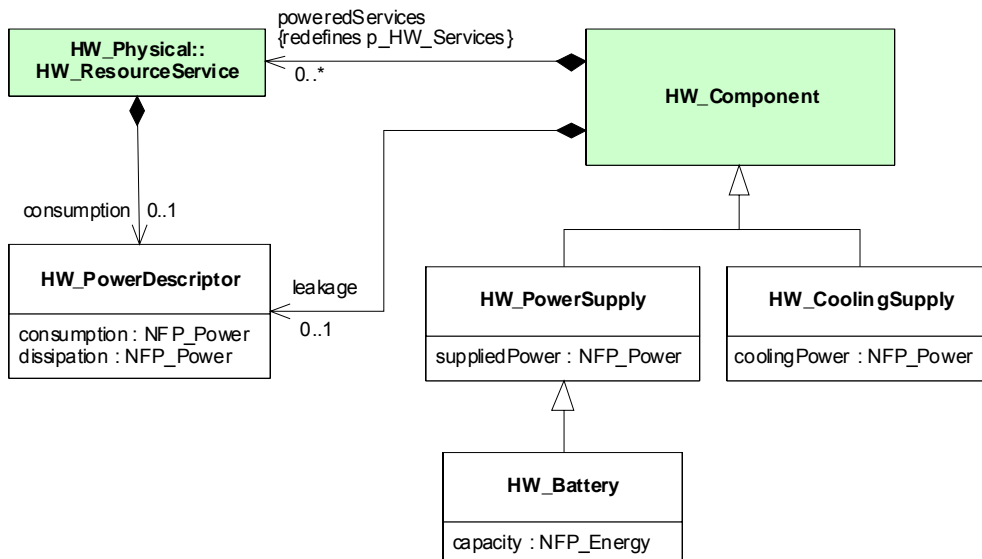

Figure 14.64 - HW_Power package details

HW_PowerDescriptor is a key metaclass that provides instantaneous power descriptions. It annotates each provided service with its corresponding consumption and each HW_Component with a description of its leakage at non-operating time.

HW_PowerSupply and HW_Battery are energy suppliers, whereas HW_CoolingSupply is a heat reducer.

14.2.3 UML representation

This section depicts the Hardware Resource Model profile. It first groups all hardware stereotypes under several profile diagrams, and then it provides the detailed description of each hardware stereotype. The Hardware Resource Model profile is based on the hardware resource domain model (on page 205). Therefore most of stereotype descriptions refer to the corresponding domain concepts. All cases where stereotypes are different from the mapped domain concepts are justified.

As shown in Figure 14.65, the Hardware Resource Model profile keeps the structure of the domain model. It is composed of logical and physical profiles. Both have a local general model of hardware platforms, in order to ensure their total independency. The logical profile is in turn composed of many other packages representing many functions of hardware, whereas the physical profile is also composed of layout and power packages. Note that these packages are not sub-profiles, they only improve the organization of the HwLogical and HwPhysical profiles.

In order to leave a large modeling flexibility, HwResource of both HwGeneral packages (Figure 14.66, Figure 14.73) inherits from the Resource stereotype (from the General Resource Model, chapter 10 on page 99) that extends the Classifier and InstanceSpecification metaclasses from the UML kernel package. This allows using the Hardware Resource Model profile within all structural UML diagrams (Class, Component, Composite Structure...) (examples 14.2.4.2, 14.2.4.3). The same principle applies to the HwResourceService that extends the Operation metaclass and could be associated with many UML behavior views.

All hardware resource stereotypes have the same extensions. However some of them are particularly also extending other appropriate UML metaclasses. E.g. HwMedia from the HwCommunication package also extends Association.

Within MARTE, stereotypes tag definitions are optional and they should be specified only if needed. In addition, because of extending both Classifier and InstanceSpecification, they could be fixed either at model or instance level. This variation point enlarges the semantics of tag definitions (battery within example 14.2.4.3).

The Hardware Resource Model profile includes many notations. There is an appropriate icon for each logical stereotype and a shape for each physical one. Also, the HwLayout package from the HwPhysical profile provides arrangement mechanisms with rectilinear grids to make UML graphical diagrams as close as possible to the real hardware platform architecture.

14.2.3.1 Profile diagrams

The Hardware Resource Model profile (HRM profile) has similar structure to the HRM domain model depicted on page 205. It is composed of logical and physical sub-profiles that contain a local general model and other different packages.

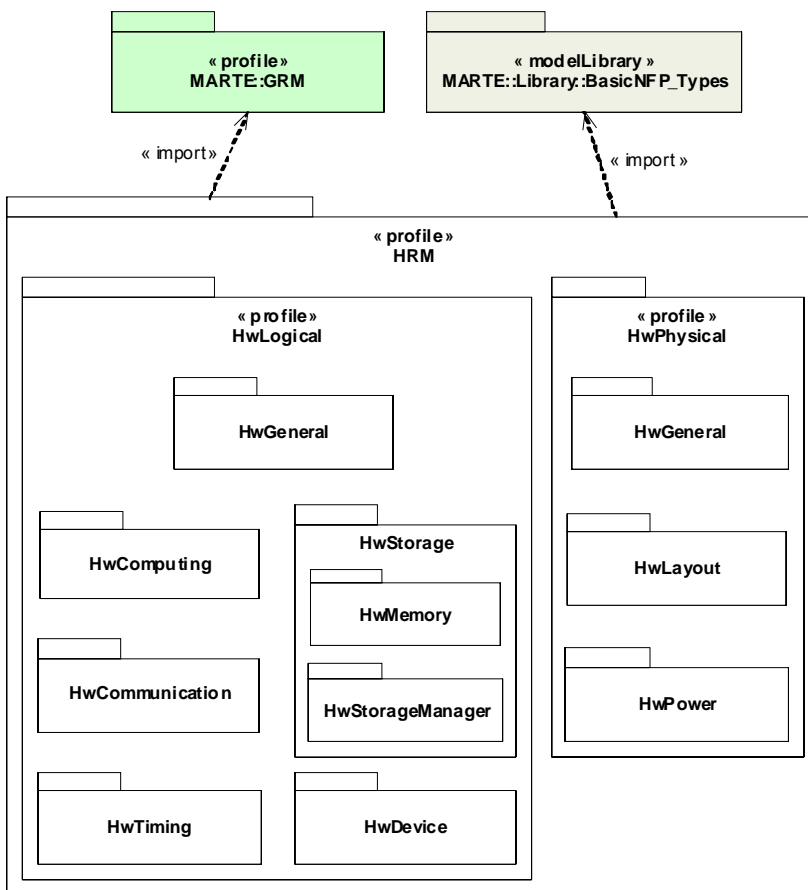

Figure 14.65 - Hardware Resource Model profile structure

HwGeneral package (from the HwLogical profile)

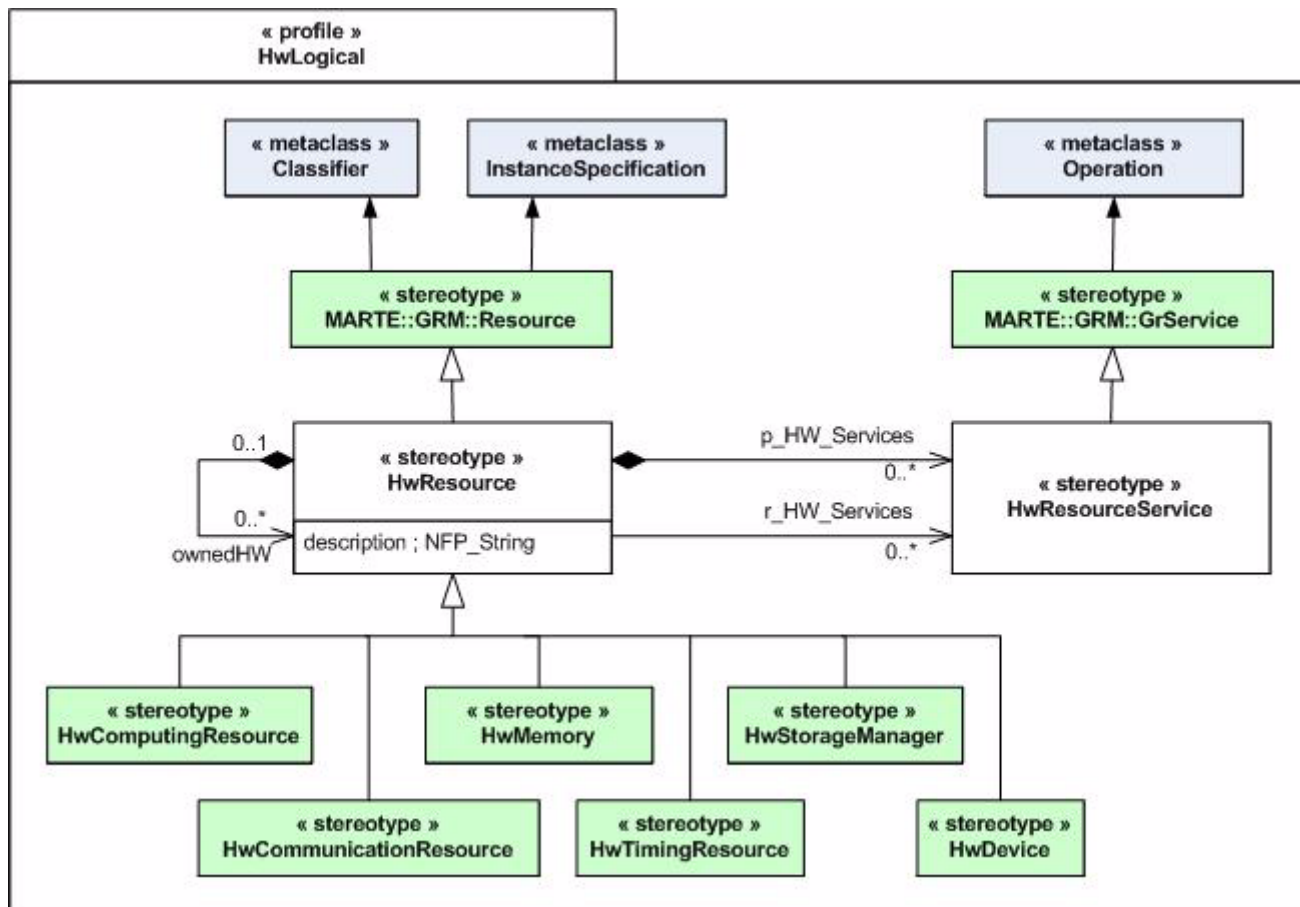

Figure 14.66 - HwGeneral package details (HwLogical)

The HwGeneral package of the HwLogical profile maps the general model from the domain view (page 206). It benefits from General Resource Model profile extensions (GRM: chapter 10, page 99) and it provides a functional classification of resources.

HwComputing package

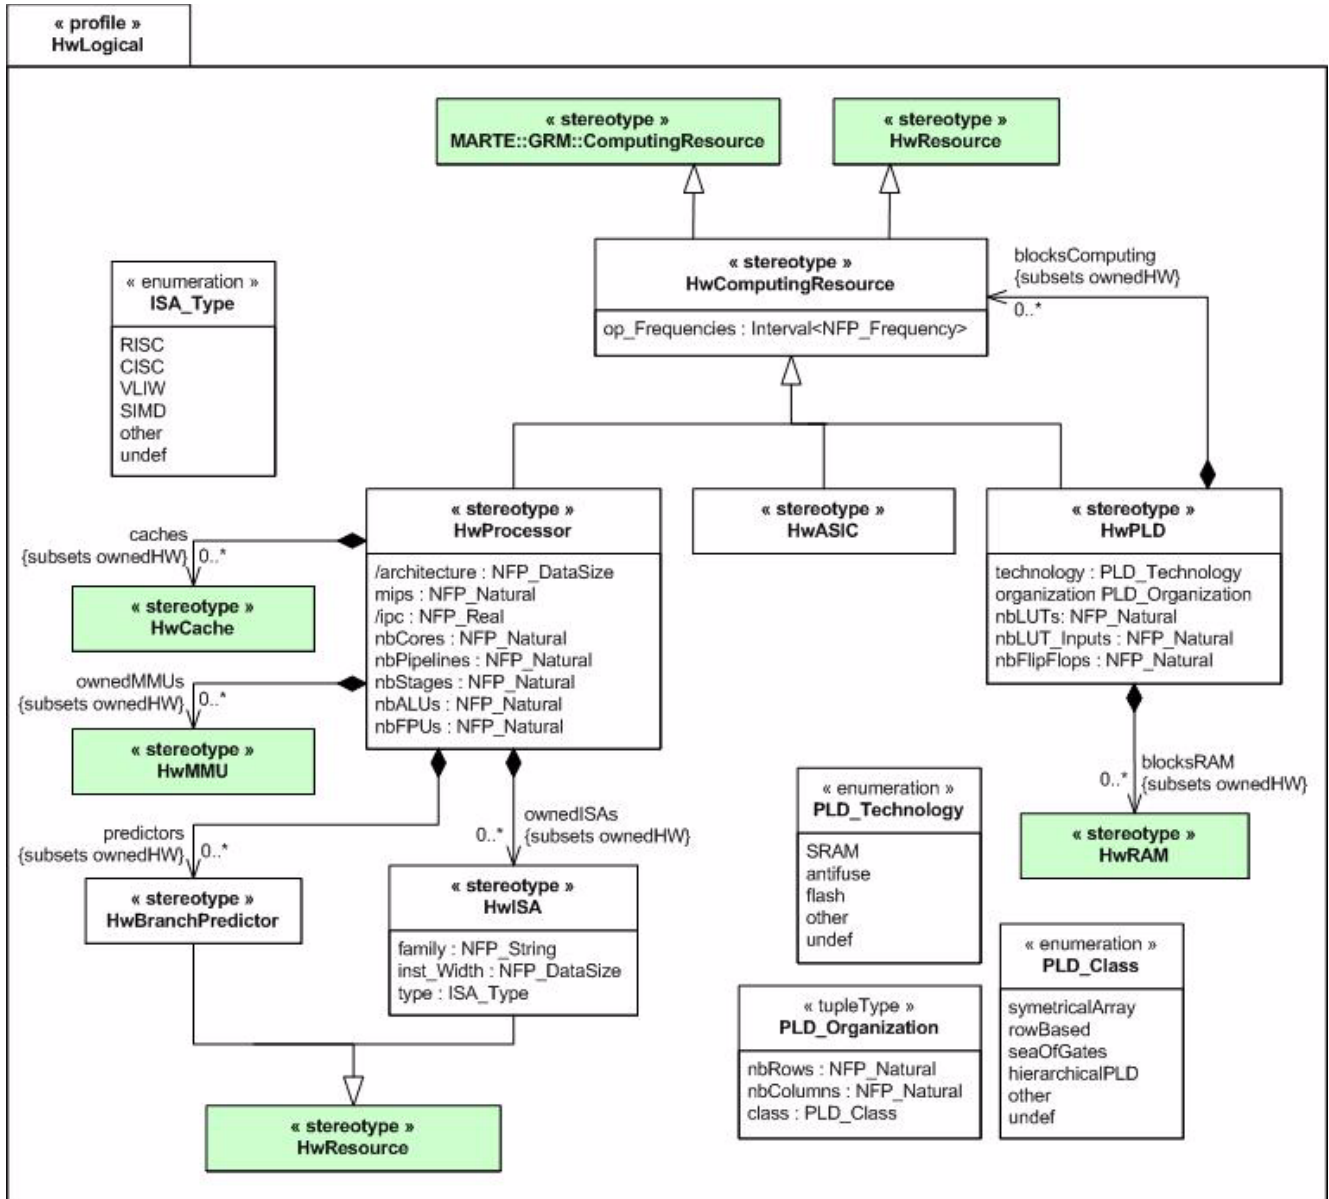

Figure 14.67 - HwComputing package details

The HwComputing package from the HwLogical profile maps the corresponding hardware computing domain model on page 207.

HwMemory package

Figure 14.68 - HwMemory package details (HwStorage)

The HwMemory package lightly varies from its corresponding domain model (page 208). It removes abstract HW_ProcessingMemory and HW_StorageMemory concepts but it maintains the composition specifying the buffer memory for the HwDrive.

HwStorageManager package

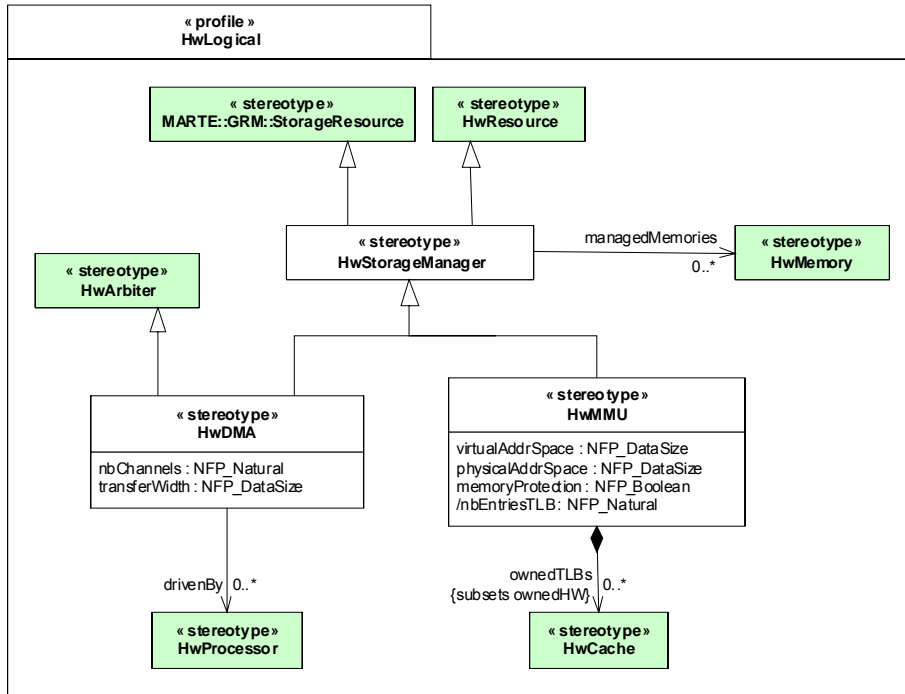

Figure 14.69 - HwStorageManager package details (HwStorage)

The HwStorageManager package from the HwLogical profile maps identically the corresponding domain model on page 209.

HwCommunication package

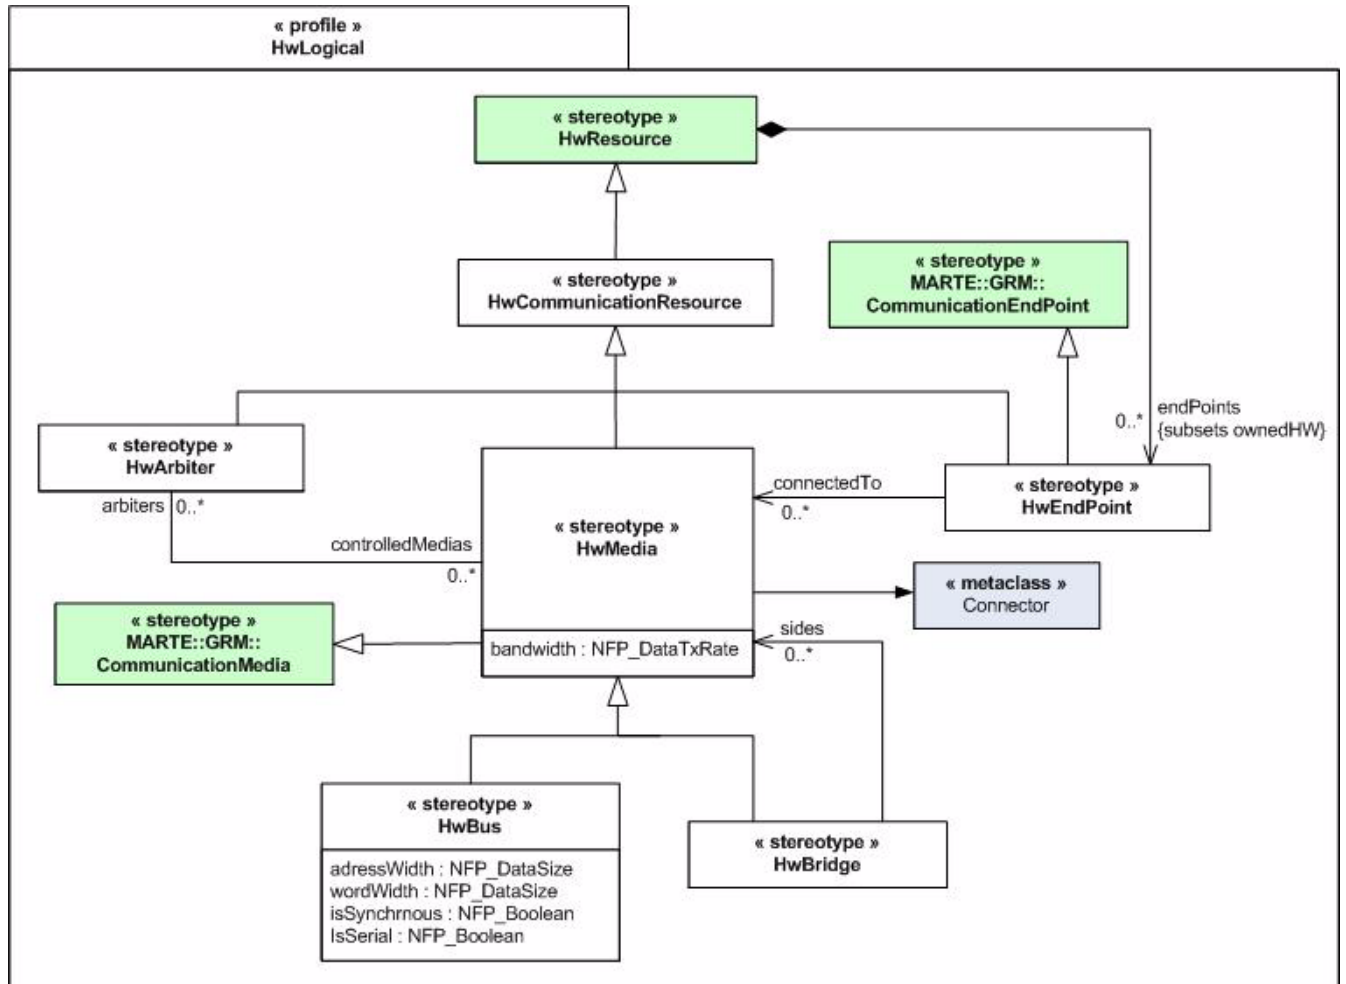

Figure 14.70 - HwCommunication package details

The HwCommunication package maps the corresponding HW_Communication domain model.

Notice that among the inherited extensions, HwMedia extends the UML Connector metaclass.

HwTiming package

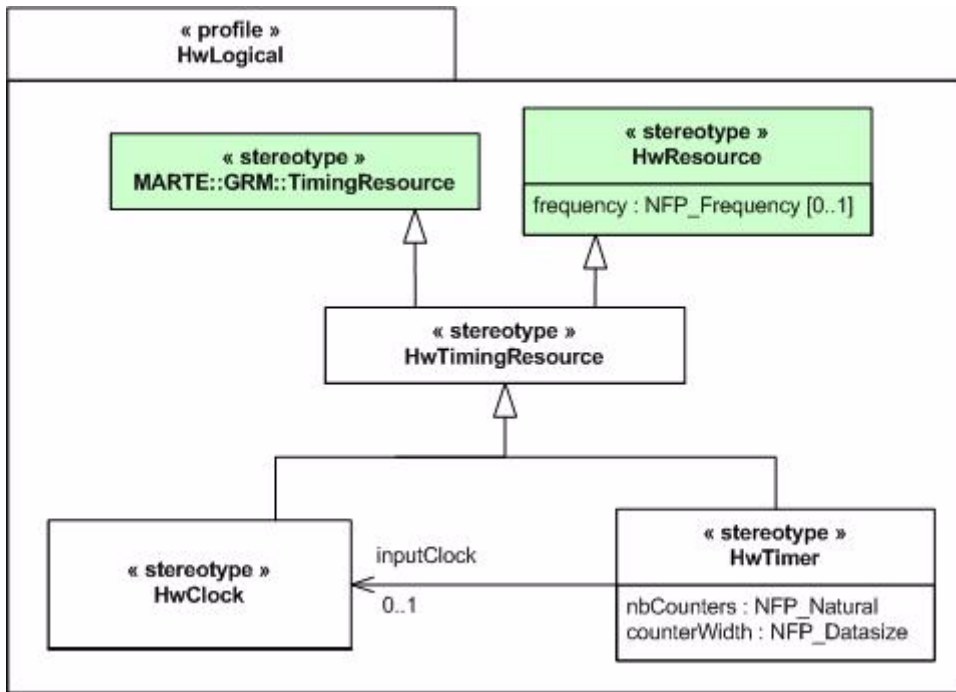

Figure 14.71 - HwTiming package details

Compared to its domain model, the association connecting an HW_Resource to an HW_Clock is substituted by an optional HwResource attribute named frequency.

As shown in example 14.2.4.1, the notifying service is the only difference between the two domain concepts HW_Timer and HW_Watchdog. Therefore, the HRM profile unifies both concepts under the HwTimer stereotype.

HwDevice package

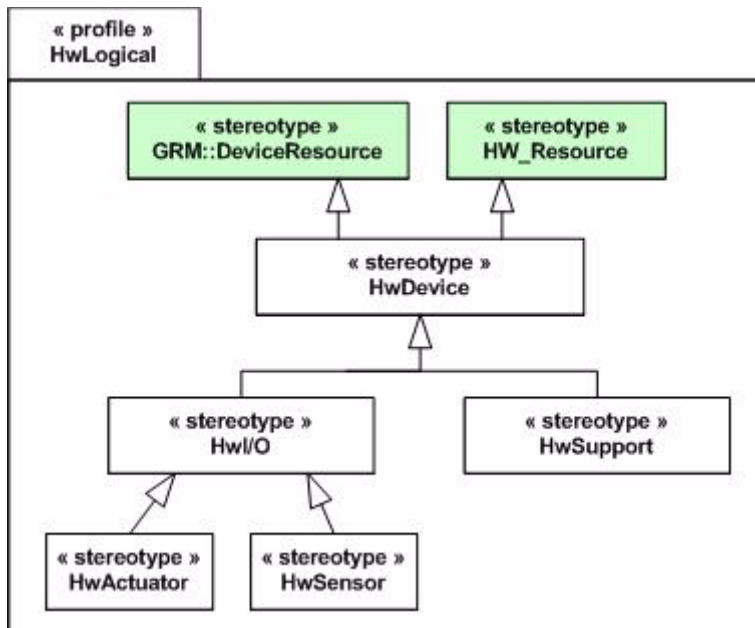

Figure 14.72 - HwDevice package details

The HwDevice package from the HwLogical profile maps the corresponding hardware device domain model.

HwGeneral package (from the HwPhysical profile)

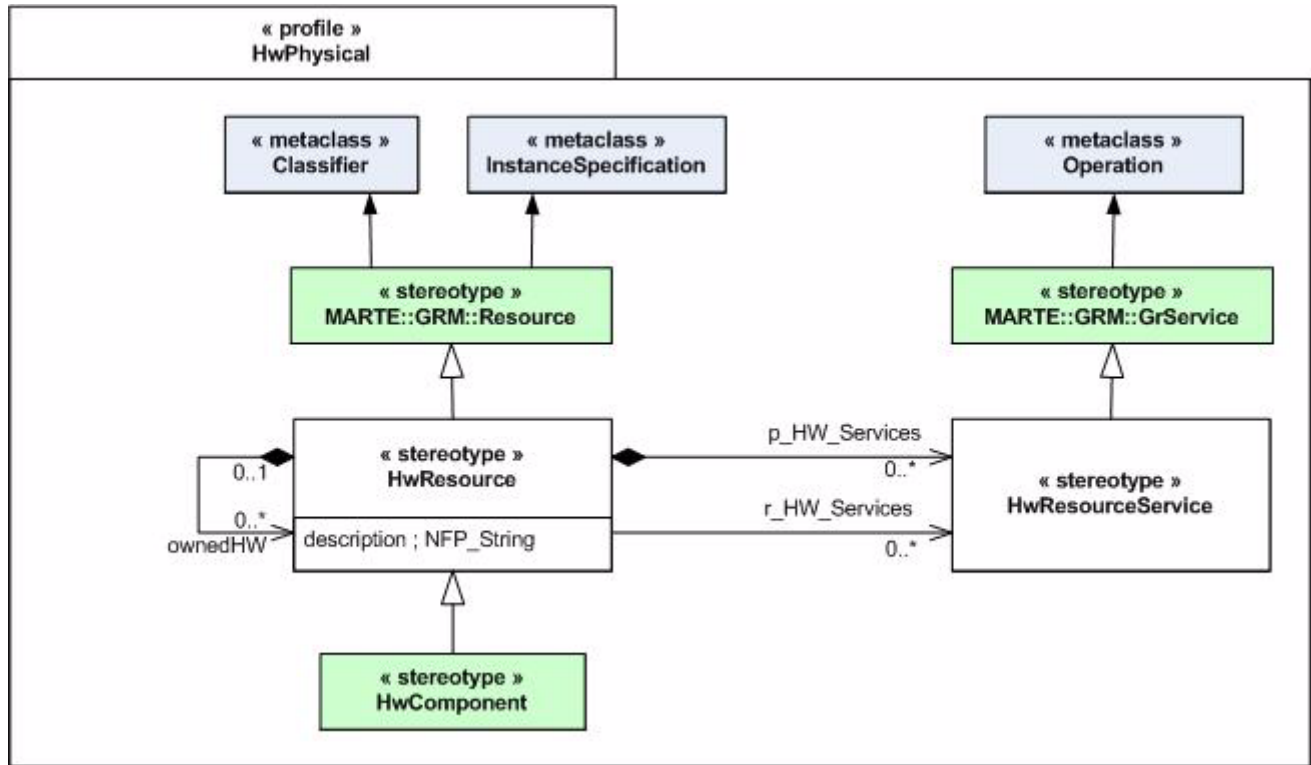

Figure 14.73 - HwGeneral package details (HwPhysical)

The HwGeneral package of the HwPhysical profile maps the general model from the domain view. It benefits from General Resource Model profile extensions (GRM: chapter 10).

HwLayout package

Figure 14.74 - HwLayout package details

Layout concepts from the HW_Layout domain model, like HW_Chip and HW_Card are grouped under the ComponentKind enumeration to lighten the profile.

HwPower package

Figure 14.75 - HwPower package details

Compared to the domain model, the HwPower package puts the HW_PowerDescriptor properties directly into the HwComponent and the HwResourceService stereotypes. It also fuses HW_Battery and HW_PowerSupply domain concepts under the same stereotype.

14.2.3.2 Stereotype descriptions

This sub-section provides a fine description of each stereotype from the Hardware Resource Profile. If a stereotype maps a domain concept, a reference is given to the corresponding page. The following list is sorted in the alphabetical order.

Note – the detailed description of concepts is mainly given in the Section F.9, “DRM::HRM,” on page 565.

CacheStructure

The CacheStructure tupletype maps the CacheStructure domain element (section F.9.1 on page 565).

Attributes

- nbSets: NFP_Natural specifies the number of sets.
- blockSize: NFP_DataSize specifies the width of a cache block.
- associativity: NFP_Natural specifies the associativity of the cache.

CacheType

The CacheType enumeration maps the CacheType domain element (section F.9.2 on page 565).

Literals

- data
- instruction
- unified for both data and instruction
- other
- undef

ComponentKind

ComponentKind is an enumeration of the following HwComponent kinds:

Description

- card
- channel
- chip
- port
- unit
- other

- undef

ComponentState

The ComponentState enumeration maps the ComponentState domain element (section F.9.3 on page 565).

Description

- operating
- storage non-operating state
- other
- undef

ConditionType

The ConditionType enumeration maps the ConditionType domain element (section F.9.4 on page 566).

Description

- temperature
- humidity
- altitude
- vibration
- shock
- other
- undef

Env_Condition

The Env_Condition tupletype maps the Env_Condition domain element (section F.9.5 on page 566).

Attributes

- type: ConditionType specifies the condition type.
- status: ComponentState specifies the required state of the HwComponent.
- description: NFP_String specifies a short description of the environmental condition.
- range: Interval<T->Real> specifies the range of possible values.

HwActuator

Actuators are frequently used as mechanisms to introduce motion, or to clamp an object so as to prevent motion. They are devices which transform an input signal (mainly an electrical signal) into motion (section F.9.6 on page 566).

Generalizations

- HwI/O

HwArbiter

The HwArbiter stereotype maps the HW_Arbiter domain element (section F.9.7 on page 567).

Generalizations

- HwCommunicationResource

Associations

- controlledMedias: HwMedia[0..*] specifies the controlled connections.

Notations

HwASIC

The HwASIC stereotype maps the HW_ASIC domain element (section F.9.8 on page 567).

Generalizations

- HwComputingResource

Constraints

[1] if a clock frequency is specified, it must belong to op_Frequencies.

HwBranchPredictor

The HwBranchPredictor stereotype maps the HW_BranchPredictor domain element (section F.9.10 on page 569).

Generalizations

- HwResource

HwBridge

The HwBridge stereotype maps the HW_Bridge domain element (section F.9.11 on page 569).

Generalizations

- HwMedia

Associations

- sides: HwMedia[0..*] specifies HwMedias at the ends of the HwBridge.

Notations

HwBus

The HwBus stereotype maps the HW_Bus domain element (section F.9.12 on page 570).

Generalizations

- HwMedia

Attributes

- `adressWidth: NFP_DataSize` specifies the supported addressing size. In general, it is a number of bits.
- `wordWidth: NFP_DataSize` specifies the transfer word width.
- `isSynchronous: NFP_Boolean` specifies whether the bus is clocked or not.
- `isSerial: NFP_Boolean` distinguishes serial from parallel buses.

Constraints

[1] Synchronous bus must have a clock frequency.

HwCache

The HwCache stereotype maps the HW_Cache domain element (section F.9.13 on page 570).

Generalizations

- HwMemory

Attributes

- `level: NFP_Natural` specifies the cache level. The default value is 1.
- `type: CacheType` specifies the type of the cache.
- `structure: CacheStructure` specifies the structure of the cache.

Constraints

[1] `memorySize` is derived from `structure` attribute.

[2] `addressSize` is greater than the total cache entries number derived from the `structure` attribute.

HwClock

The HwClock stereotype maps the HW_Clock domain element (section F.9.17 on page 572).

Generalizations

- HwTimingResource

Attributes

- None.

HwCommunicationResource

The HwCommunicationResource stereotype maps the HW_CommunicationResource domain element (section F.9.18 on page 573).

Generalizations

- HwResource

HwComponent

The HwComponent stereotype maps the HW_Component domain element from the HW_Layout package (section F.9.19 on page 573).

Generalizations

- HwResource

Associations

- subComponents: HwComponent[0..*]
specifies the owned physical entities. Subsets HwResource.ownedHW.

Attributes

- dimensions: NFP_Length[0..3]
specifies Cartesian dimensions of the HwComponent. It is an ordered attribute.
- /area: NFP_Area
specifies the area of the HwComponent. Derived from dimensions.
- position: Interval<NFP_Natural>[0..2]
specifies position within the enclosing HwComponent. It is an ordered attribute.
- grid: NFP_Natural[0..2]
specifies a rectilinear grid associated to the HwComponent. It is an ordered attribute.
- nbPins: NFP_Natural[0..1]
specifies the number of pins. It is optional.
- weight: NFP_Weight
specifies the weight of the HwComponent.
- price: NFP_Price
specifies the HwComponent price.

- `r_Conditions`: `Env_Condition[*]`
specifies the required environmental conditions.
- `kind`: `ComponentKind`
specifies the kind of the `HwComponent`
- `staticConsumption`: `NFP_Power`
specifies the `HwComponent` static consumption.
- `staticDissipation`: `NFP_Power`
specifies the `HwComponent` static dissipation.

Semantics

The `HwComponent` stereotype maps its corresponding domain concept but it has Three additional attributes, `kind` to specify the kind of the hardware component, `staticConsumption` and `staticDissipation` that are appropriate for power description and substitute the composition between the `HW_Component` and `HW_PowerDescriptor` domain concepts.

Constraints

- [1] `area` must derive from dimensions.
- [2] `subComponents` positions must not exceed the grid.
- [3] `requiredConditions` intervals must be included within the subcomponents corresponding intervals.

Notations

`HwComponent` has many shapes depending on its kind.

- Card

- Channel

- Chip

- Port

Each composite class stereotyped with "HW_Component" may be considered as a rectilinear grid where its parts are located in their corresponding positions. Hence, one propose an extension to the notation of composite class in order to take into account this feature as depicted below and illustrated through an example in Figure 14.83. This proposed notation is similar to the one of the Region concept of UML state machine diagram.

HwComputingResource

The HwComputingResource stereotype maps the HW_ComputingResource domain element (section F.9.21 on page 575).

Generalizations

- MARTE::GRM::ComputingResource
- HwResource

Attributes

- op_Frequencies : Interval<NFP_Frequency>specifies the range of supported frequencies.

Constraints

[9] if a clock frequency is specified, it must belong to op_Frequencies.

Notations

Figure 14.76 - HwCoolingSupply

HwCoolingSupply

The HwCoolingSupply stereotype maps the HW_CoolingSupply domain element (section F.9.22 on page 576).

Generalizations

- HwComponent

Attributes

- coolingPower: NFP_Power specifies the cooling power.

Notations

HwDevice

The HwDevice stereotype maps the HW_Device domain element (section F.9.23 on page 576).

Generalizations

- MARTE::GRM::DeviceResource
- HwResource

Notations

HwDMA

The HwDMA stereotype maps the HW_DMA domain element (section F.9.24 on page 577).

Generalizations

- HwStorageManager
- HwArbiter

Associations

- drivenBy: HwProcessor[0..*] specifies processors that control the HwDMA.

Attributes

- nbChannels: NFP_Natural specifies the number of HwDMA channels.
- transferWidth: NFP_DataSize specifies the maximum supported transfer width.

HwDrive

The HwDrive stereotype maps the HW_Drive domain element (section F.9.25 on page 577).

Generalizations

- HwMemory

Associations

- buffer: HwRAM[0..1] specifies the memory buffer of the HwDrive. Subsets HwResource::ownedHW.

Attributes

- sectorSize : NFP_DataSize specifies the sector size of the HwDrive.

Semantics

An HwDrive may own an HwRAM as a memory buffer. This composition substitutes the one from the domain model between the HW_ProcessingMemory and HW_StorageMemory concepts.

HwEndPoint

The HwEndPoint stereotype maps the HW_EndPoint domain element (section F.9.26 on page 578).

Generalizations

- MARTE::GRM::CommunicationEndPoint
- HwCommunicationResource

Associations

- connectedTo: HwMedia[0..*] specifies the communication medias that the end point is connected to.

HwI/O

The HwI/O stereotype maps the HW_I/O domain element (section F.9.27 on page 578).

Generalizations

- HwDevice

Notations

HwISA

The HwISA stereotype maps the HW_ISA domain element (section F.9.28 on page 579).

Generalizations

- HwResource

Attributes

- family: NFP_String specifies the ISA family.
- inst_Width: NFP_DataSize specifies the instruction width
- type: ISA_Type specifies the ISA type

HwMedia

The HwMedia stereotype maps the HW_Media domain element (section F.9.29 on page 579).

Generalizations

- MARTE::GRM::CommunicationMedia
- HwCommunicationResource

Extensions

- Connector (from UML::InternalStructures)

Associations

- arbiters: HwArbiter[0..*] specifies the HwMedia controllers.

Attributes

- None.

Notations

HwMemory

The HwMemory stereotype maps the HW_Memory domain element (section F.9.30 on page 580).

Generalizations

- MARTE::GRM::StorageResource
- HwResource

Attributes

- memorySize: NFP_DataSize specifies the storage capacity of the HwMemory.
- addressSize: NFP_DataSize specifies the address width of the HwMemory.
- timings: Timing[*] specifies timings of the HwMemory.
- throughput:NFP_DataTxRate specifies the throughput in a memory.

Constraints

[10] the value of the inherited attribute isprotected is true.

Notations

HwMMU

The HwMMU stereotype maps the HW_MMU domain element (section F.9.31 on page 581).

Generalizations

- HwStorageManager

Associations

- ownedTLBs: HwCache[0..*] specifies the owned Translation Lookaside Buffers.

Attributes

- virtualAddrSpace: NFP_DataSize specifies the managed virtual address space.
- physicalAddrSpace: NFP_DataSize specifies the managed physical address space.

- memoryProtection: NFP_Boolean specifies if memory protection is supported.
- /nbEntriesTLB: NFP_Natural specifies the total number of TLBs entries. Derived from the ownedTLBs association.

Constraints

[1] nbEntriesTLB is derived from the ownedTLBs number of entries.

HwPLD

The HwPLD stereotype maps the HW_PLD domain element (section F.9.32 on page 581).

Generalizations

- HwComputingResource

Associations

- blocksComputing: HwComputingResource[0..*]
specifies owned computing blocks. Subsets HwResource.ownedHW.
- blocksRAM : HwRAM[0..*]
specifies the owned HwRAM memories.

Attributes

- technology: PLD_Technology specifies the HwPLD technology.
- organization: PLD_Organization specifies the matrix organization of the HwPLD.
- nbLUTs specifies the number of LUTs within the HwPLD.
- nbLUT_Inputs specifies the number of inputs of one LUT.
- nbFlipFlops specifies the number of FlipFlops within the HwPLD.

Constraints

[1] if a clock frequency is specified, it must belong to op_Frequencies.

HwPowerSupply

The HwPowerSupply stereotype maps the HW_PowerSupply domain element (section F.9.35 on page 583).

Generalizations

- HwComponent

Attributes

- suppliedPower: NFP_Power specifies the instantaneous supplied power.
- capacity: NFP_Energy[0..1] specifies the capacity of the HwPowerSupply.

Semantics

This stereotype denotes both domain elements HW_PowerSupply and HW_Battery.

Constraints

[1] power consumption is greater than dissipation.

Notations

HwProcessor

The HwProcessor stereotype maps the HW_Processor domain element (section F.9.37 on page 584).

Generalizations

- HwComputingResource

Associations

- predictors: HwBranchPredictor[0..*] specifies the owned branch prediction units. Subsets HwResource.ownedHW.
- caches: HwCache[0..*] specifies processor caches. Subsets HwResource.ownedHW.
- ownedMMUs: HwMMU[0..*] specifies the owned Memory Management Units. Subsets HwResource.ownedHW.
- ownedISAs: HwISA[1..*] specifies the owned instruction set architectures. Subsets HwResource.ownedHW.

Attributes

- /architecture: NFP_DataSize specifies the instruction width. Derived from ownedISAs.
- mips: NFP_Natural specifies the throughput of the processor.
- /ipc: NFP_Real specifies the number of instructions executed each clock cycle. Derived from mips and clock attributes.
- nbCores: NFP_Natural specifies the number of cores within the HwProcessor.
- nbPipelines: NFP_Natural specifies the number of pipelines per core.
- nbStages: NFP_Natural specifies the number of stages per pipeline.
- nbALUs: NFP_Natural specifies the number of Arithmetic Logic Units within the HwProcessor.
- nbFPUs: NFP_Natural specifies the number of Floating Point Units within the HwProcessor.

Constraints

- [1] if a clock frequency is specified, it must belong to op_Frequencies.
- [2] architecture must derive from the inst_Width of the supportedISAs.
- [3] ipc must derive from mips attribute and clock frequency.

HwRAM

The HwRAM stereotype maps the HW_RAM domain element (section F.9.38 on page 586).

Generalizations

- HwMemory

Attributes

- organization: MemoryOrganization specifies the organization of the HwRAM.
- isSynchronous: NFP_Boolean specifies whether the HwAM is clocked or not.
- isStatic: NFP_Boolean specifies whether the HwRAM is static or not.
- isNonVolatile: NFP_Boolean specifies whether the HwRAM is volatile or not. Default value is false.

Constraints

- [1] memorySize is derived from organization attribute.
- [2] addressSize is greater than the number of memory words derived from organization attribute.
- [3] synchronous HwRAM must have a clock frequency.

HwResource (from HwLogical)

This HwResource stereotype maps the HW_Resource domain element from the HW_Logical package (section F.9.39).

Generalizations

- MARTE::GRM::Resource.

Associations

- ownedHW: HwResource[0..*] specifies the owned sub-HwResources. Subsets Resource.ownedElement.
- p_HW_Services: HwResourceService[0..*] specifies the provided services. Subsets Resource.pServices.
- r_HW_Services: HwResourceService[0..*] specifies the required services.
- endPoints: HwEndPoint[0..*] specifies the connection points of the HwResource. Subsets ownedHW.

Attributes

- description: NFP_String specifies a textual description of the HwResource.
- frequency: NFP_Frequency[0..1] specifies the clock frequency of the HwResource.

HwResource (from HwPhysical)

This HwResource stereotype maps the HW_Resource domain element from the HW_General package (section F.9.41 on page 588).

Generalizations

- MARTE::GRM::Resource.

Associations

- ownedHW: HwResource[0..*] specifies the owned sub-HwResources. Subsets Resource.ownedElement.
- p_HW_Services: HwResourceService[0..*] specifies the provided services. Subsets Resource.pServices.
- r_HW_Services: HwResourceService[0..*] specifies the required services.

Attributes

- description: NFP_String specifies a textual description of the HwResource.

HwResourceService (from HwLogical)

The HwResourceService stereotype maps the HW_ResourceService domain element from the HW_General package (section F.9.41 on page 588).

Generalizations

- MARTE::GRM::ResourceService

HwResourceService (from HwPhysical)

The HwResourceService stereotype maps the HW_ResourceService domain element from the HW_Physical package (section F.9.42 on page 588).

Generalizations

- MARTE::GRM::ResourceService

Attributes

- consumption: NFP_Power specifies the consumption of the HwComponent when powering the HwResourceService.
- dissipation: NFP_Power specifies the dissipation of the HwComponent when powering the HwResourceService.

Semantics

Compared to its analogous domain concept, the HwResourceService stereotype from the HwPhysical package converts the association with the HW_PowerDescriptor to two appropriate attributes.

Constraints

[1] power consumption is greater than dissipation.

HwROM

The HwROM stereotype maps the HW_ROM domain element (section F.9.43 on page 589).

Generalizations

- HwMemory.

Attributes

- type: ROM_Type specifies the HwROM type.
- organization: MemoryOrganization specifies the structure of the HwROM.

Constraints

[1] memorySize is derived from organization attribute.

[2] addressSize is greater than the number of memory words derived from organization attribute.

HwSensor

A sensor is a device that measures a physical quantity and converts it into a signal, which can be read by an observer or by an instrument. (section F.9.X).

Generalizations

- HwI/O

HwStorageManager

The HwStorageManager stereotype maps the HW_StorageManager domain element (section F.9.44 on page 589).

Generalizations

- MARTE::GRM::StorageResource
- HwResource

Associations

- managedMemories: HwMemory[0..*] specifies the managed memories.

Notations

HwSupport

The HwSupport stereotype maps the HW_Support domain element (section F.9.47 on page 591).

Generalizations

- HwDevice

HwTimer

The HwTimer stereotype maps the HW_Timer domain element (section F.9.48 on page 592).

Generalizations

- HwTimingResource

Associations

- inputClock: HwClock[0..1] specifies the input clock of the HwTimer.

Attributes

- nbCounters: NFP_Natural specifies the number of counters within the HwTimer.
- counterWidth: NFP_DataSize specifies the width of one counter.

Semantics

This stereotype unifies both domain elements HW_Timer and HW_Watchdog.

HwTimingResource

The HwTimingResource stereotype maps the HW_TimingResource domain element (section F.9.49 on page 592).

Generalizations

- MARTE::GRM::TimingResource
- HwResource

Notations

ISA_Type

The ISA_Type enumeration maps the ISA_Type domain element (section F.9.52 on page 594).

Description

- RISC (Reduced Instruction Set Computer)
- CISC (Complex Instruction Set Computer)
- VLIW (Very Long Instruction Word)

- SIMD (Single Instruction Multiple Data)
- other
- undef

MemoryOrganization

The MemoryOrganization tupletype maps the MemoryOrganization domain element (section F.9.53 on page 594).

Attributes

- nbRows: NFP_Natural specifies the number of rows.
- nbColumns: NFP_Natural specifies the number of columns.
- nbBanks: NFP_Natural specifies the number of banks.

PLD_Class

The PLD_Class enumeration maps the PLD_Class domain element (section F.9.54 on page 595).

Description

- symmetricalArray
- rowBased
- seaOfGates
- hierarchicalPLD
- other
- undef

PLD_Organization

The PLD_Organization tupletype maps the PLD_Organization domain element (section F.9.55 on page 595).

Attributes

- nbRows: NFP_Natural specifies the number of rows.
- nbColumns: NFP_Natural specifies the number of columns.
- class: PLD_Class specifies the HW_PLD Class.

PLD_Technology

The PLD_Technology enumeration maps the PLD_Technology domain element (section F.9.56 on page 596).

Description

- SRAM
- Antifuse

- Flash
- other
- undef

Repl_Policy

The Repl_Policy enumeration maps the Repl_Policy domain element (section F.9.58 on page 596).

Description

- LRU Least Recently Used
- NFU Not Frequently Used
- FIFO First In First Out
- Random
- other
- undef

ROM_Type

The ROM_Type enumeration maps the ROM_Type domain element (section F.9.59 on page 596).

Description

- maskedROM
- EPROM (Erasable Programmable ROM)
- OTP_EEPROM (One Time Programmable EPROM)
- EEPROM (Electrically EPROM)
- flash
- other
- undef

Timing

The Timing tupletype maps the Timing domain element (section F.9.60 on page 597).

Attributes

- notation: NFP_String specifies the Timing notation.
- description: NFP_String specifies a short description of the Timing.
- value: NFP_Duration specifies the duration value of the Timing.

WritePolicy

The WritePolicy enumeration maps the WritePolicy domain element (section F.9.61 on page 597).

Description

- writeBack
- writeThrough
- other
- undef

14.2.4 Examples

This section contains examples implementing the Hardware Resource Model profile. These examples may help users to model a given hardware platform or to design a new one using the set of stereotypes detailed above.

In order to leave a large modeling flexibility, the HRM profile can be applied on all structural UML diagrams: Class (example 14.2.4.2), Component, Composite Structure(example 14.2.4.3).

At the end, notice that the OMG standard XML Metadata Interchange (XMI) eases exchanging metadata of UML models. It is now supported by most UML-based modeling tools. The XMI also eases model transformation, parsing and code generation, consequently, many tools affords mechanisms to extract data from UML models for analysis, simulation or implementation purposes.

14.2.4.1 Resource services

Within the domain view, the resource services (HW_ResourceService) are not explicitly specified as they are mainly deduced from the nature of the resource and they should be fully listed only if such level of detail is needed. The logical view classifies hardware resources depending on their functional role within the execution platform and the services they are offering.

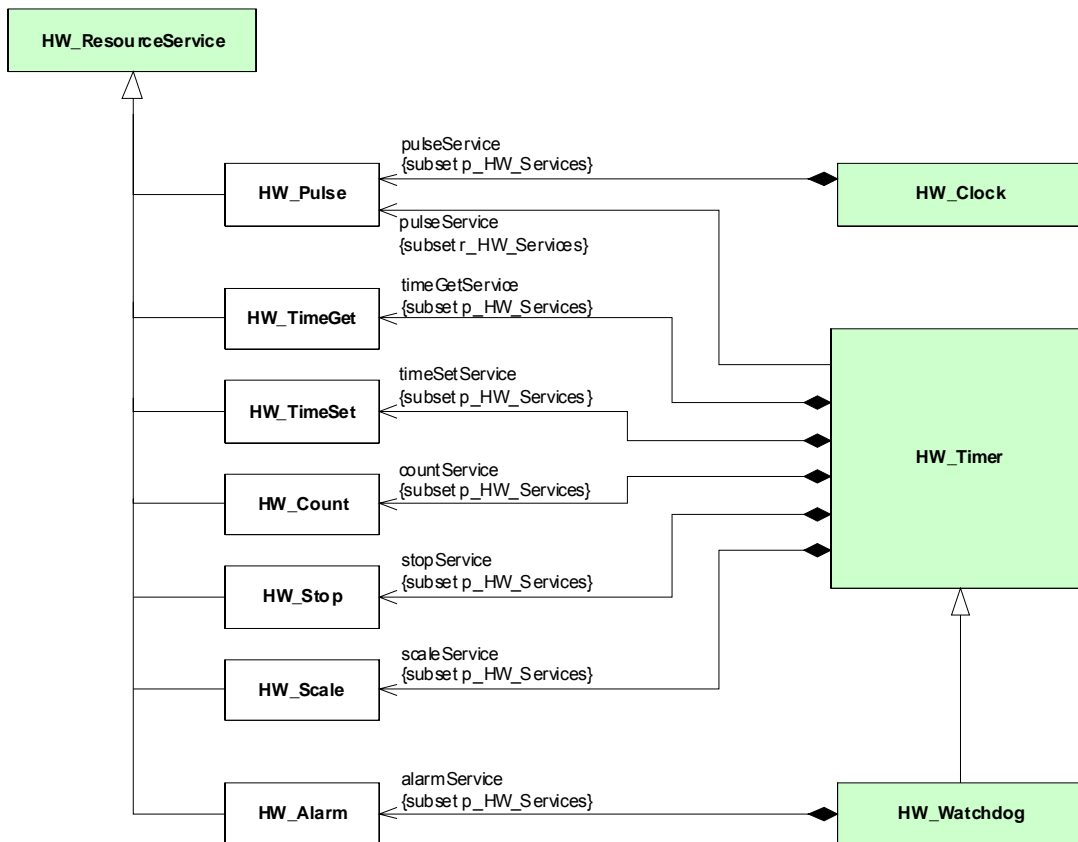

Figure 14.77 - Resource services example (HW_Timing)

Figure 14.76 gives a detailed description of required and provided services of timing resources (Figure 14.60). An HW_Timer requires an HW_Pulse service offered by the HW_Clock and provides at least:

- HW_TimeGet service to get the current time.
- HW_TimeSet service to set a new time value given as parameter.
- HW_Count service to start counting.
- HW_Stop service to stop counting.
- HW_Scale service to set a counting scale, it needs a number of clocks as parameter.

An HW_Watchdog is an HW_Timer providing an additional notifying service HW_Alarm.

14.2.4.2 Stereotype application

Figure 14.77 shows a three steps example of applying the HwRAM stereotype.

(a) is part of the detailed HwStorage metamodel, it collects properties common to all memory technologies.

(b) defines the SDRAM (short for Synchronous Dynamic Random Access Memory) technology as a model where a part of tagged values (e.g. isNonVolatil, isSynchronous and isStatic) are fixed. Other specific attributes are added at this level to refine the SDRAM class (burst transfers and refresh modes).

(c) is the final step where we instantiate a particular memory card from of the SDRAM technology model. Here is a real example of specific Samsung SDRAM.

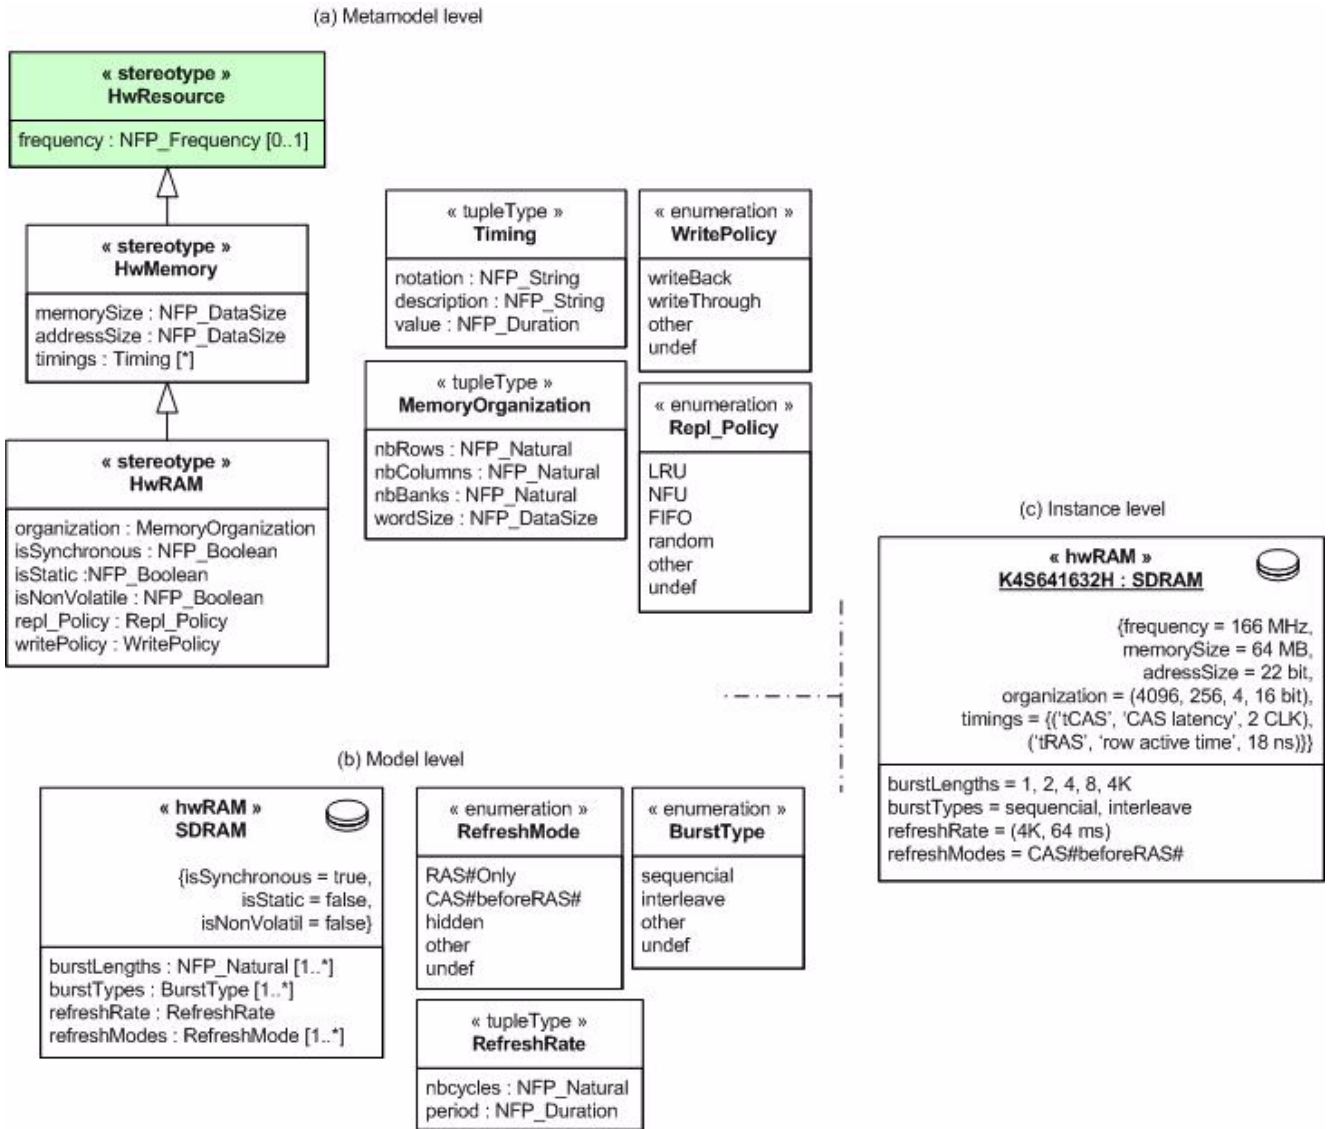

Figure 14.78 - Stereotype application example (SDRAM)

14.2.4.3 Logical/Physical modeling

The next example is an SMP (Symmetric MultiProcessing) hardware platform with four processors owning caches and sharing the same main memory, through an FSB bus. This SMP platform also contains a 4-channels DMA (Direct Memory Access) and a battery (Figure 14.78).

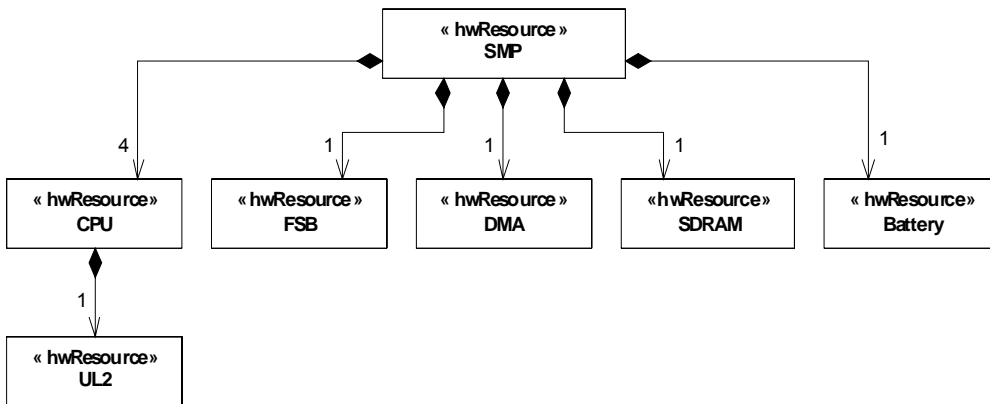

Figure 14.79 - SMP description

Next figures depicts two refinements of the previous high level model into a logical view on Figure 14.79 and a physical view on Figure 14.80.

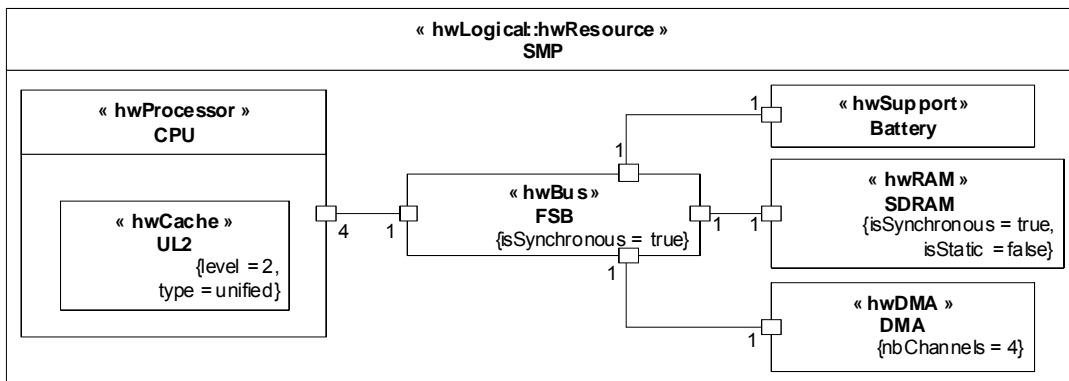

Figure 14.80 - SMP logical view

Due to its encapsulation/composition mechanisms, the UML Composite Structure diagram is well adapted to hardware modelling even if the HRM profile can be used with all structural diagrams.

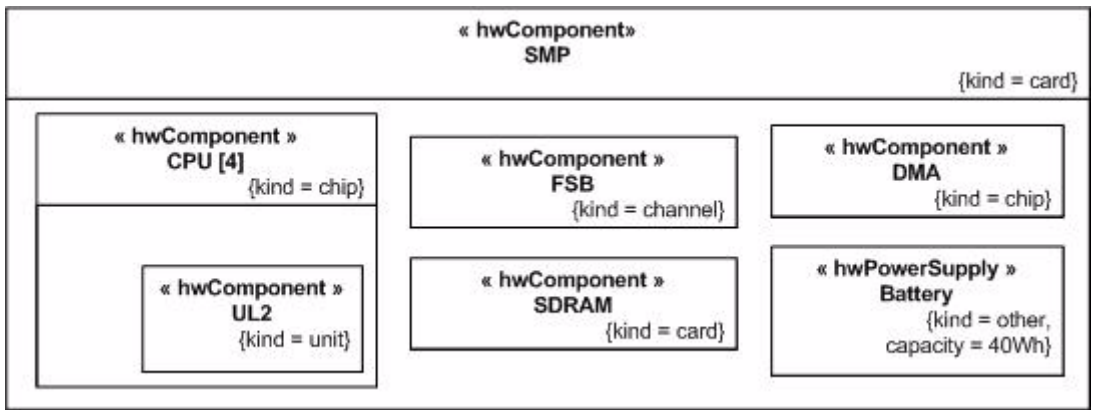

Figure 14.81 - SMP physical view

As UML allows application of many stereotypes on the same element, these two previous views could be merged into a unified view as shown in Figure 14.81.

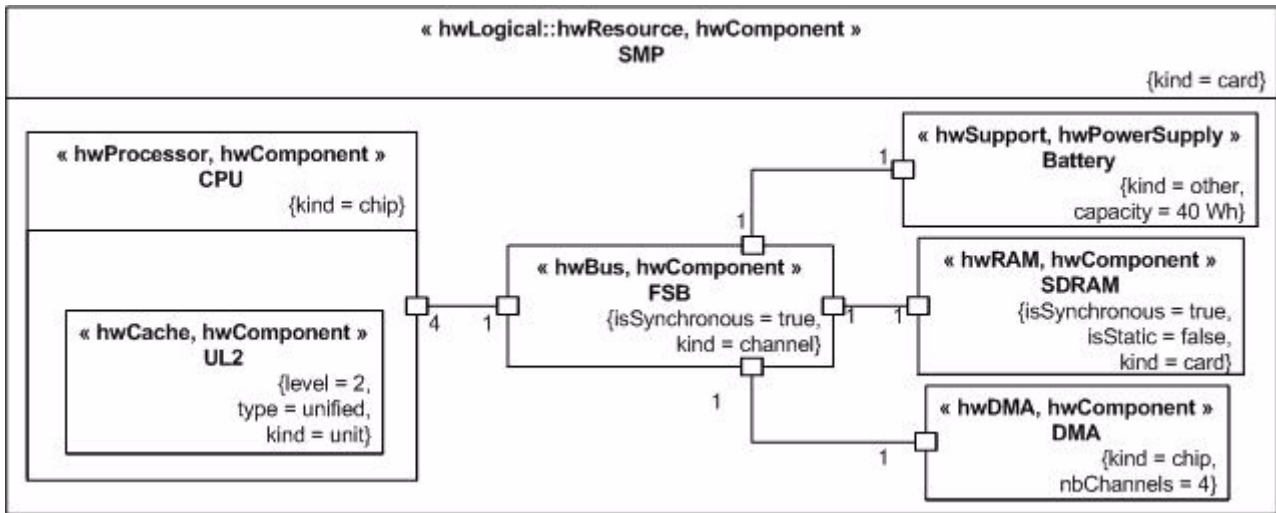

Figure 14.82 - SMP merged (logical/physical) view

Even if merging logical and physical views is possible, separation of concerns is an adequate way to have specialized and detailed models that are lightened from unused properties. Figure 14.82 and Figure 14.83 depict two detailed logical and physical refinements of the SMP example introduced above.

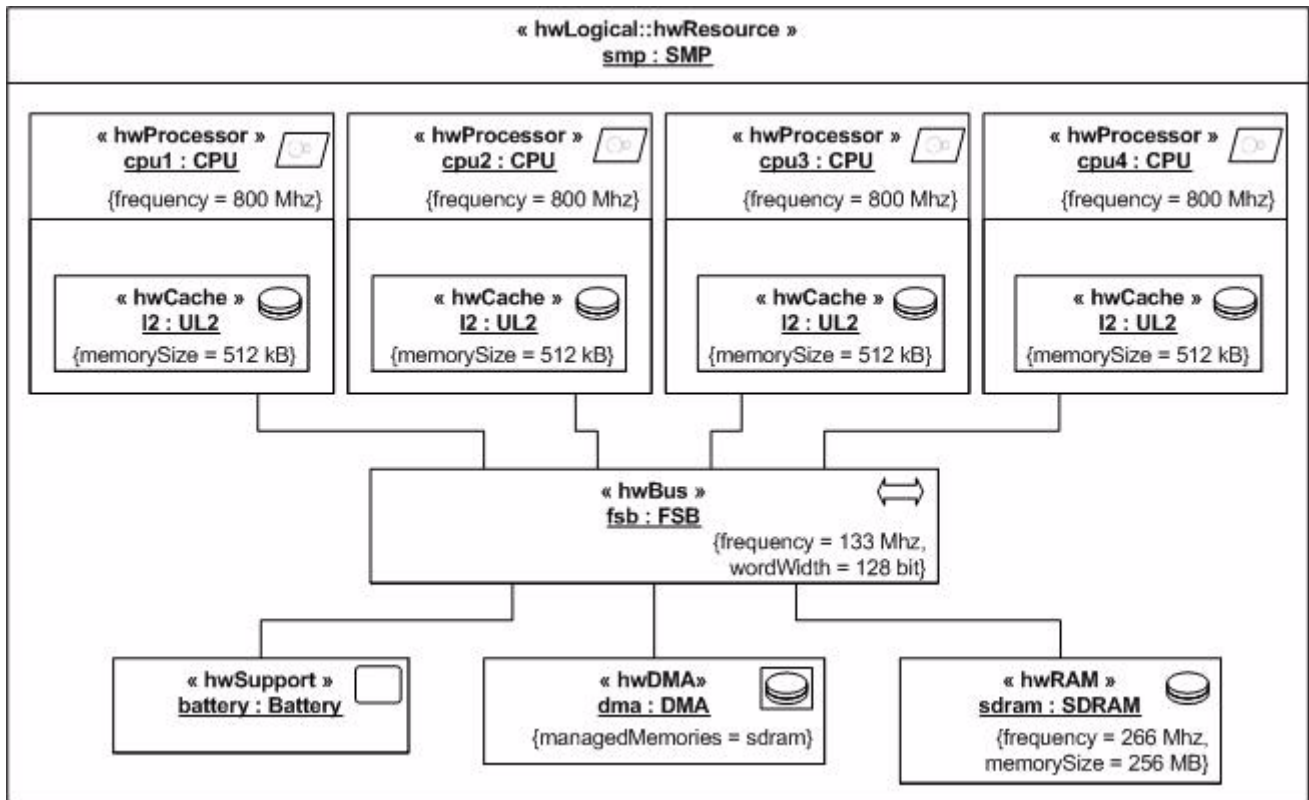

Figure 14.83 - SMP detailed logical model

The HRM includes many notations (icons and shapes), the physical view provides arrangement mechanisms to make UML graphical diagrams as close as possible to the real hardware platform architecture. The physical view on Figure 14.83 illustrates these profile features.

Figure 14.84 - SMP detailed physical model

Because of the nature of hardware resources, the logical and physical views converge on many concepts. Some logical stereotypes have a set of corresponding physical stereotypes like an `HwLogical::HwBus` which is typically a physical channel or `HwLogical::HwProcessor(s)` that are chips. Reciprocally, an `HwPhysical::HwBattery` is considered as an `HwLogical::HwSupport` device. More accurately, the `addressSize` and `wordSize` tag values of an `HwLogical::HwMemory` must go with the `nbPins` tag value of the corresponding `HwPhysical::HW_Component`.

Within MARTE, stereotypes tag values can be fixed either at model or instance level. This enlarges the semantics of hardware models. For example, within Figure 14.80, the capacity of the battery at the model level was 40Wh and corresponds to the maximum capacity of such class of batteries, whereas the same tag value becomes 10Wh at instance level (Figure 14.83) and represents the current stored energy.

Part III - MARTE Analysis Model

This Part contains the following chapters:

- 15 - Generic Quantitative Analysis Modeling (GQAM)
- 16 - Schedulability Analysis Modeling (SAM)
- 17 - Performance Analysis Modeling (PAM)

15 Generic Quantitative Analysis Modeling (GQAM)

The generic analysis domain includes specialized domains in which the analysis is based on the software behaviour, such as performance and schedulability (the two next chapters), and also power, memory, reliability, availability and security. Although analysis domains have different terminology, concepts, and semantics, they also share some foundation concepts which are expressed in this chapter, in order to simplify the profile and make it easier to add new analyses. Generic modeling defines basic modeling concepts and NFPs, using the NFP annotation framework depicted in section 8 on page 51.

MARTE analysis is intended to support accurate and trustworthy evaluations using formal quantitative analyses based on sound mathematical models, which may supplement designer intuition and "feel." Model analysis can detect problems early in the development life cycle and reduce cost and risk.

The two following chapters use GQAM in creating sub-profiles for:

- Schedulability analysis, to predict whether a set of software tasks meets its timing constraints and to verify its temporal correctness, e.g., RMA-based techniques (see, e.g., "Real-Time Systems", by Jane Liu).
- Performance analysis, to determine if a system with non-deterministic behavior can provide adequate performance, usually defined by some statistical measures (see e.g., The Art of Computer Performance Modeling, by Raj Jain).

Figure 15-1 shows the relationship of these chapters to each other and to the rest of the profile. Analysis of power consumption and the use of memory are also briefly considered here as additional specializations that may be used in future analysis subprofiles.

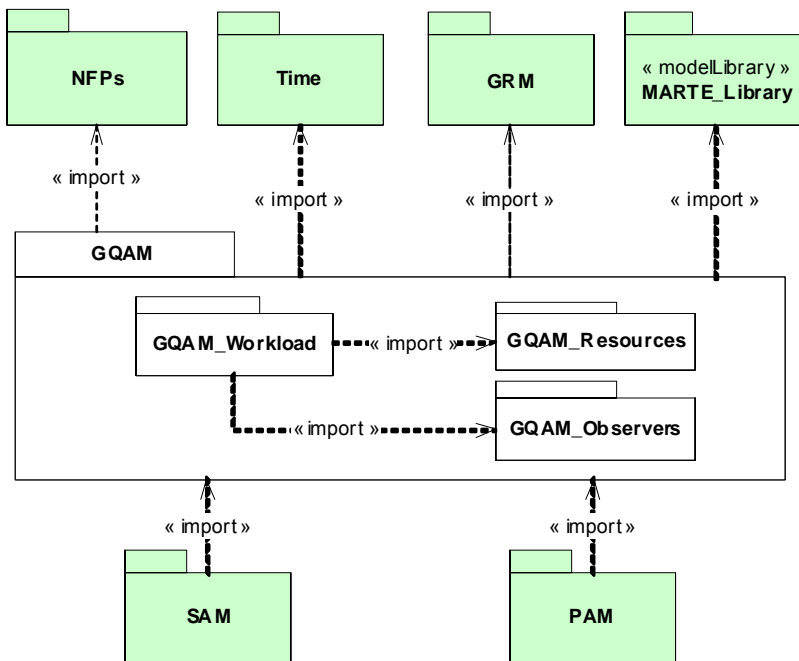

Figure 15.1 - Dependencies of GenericQuantitativeAnalysisModeling (GQAM) package

15.1 Overview

This chapter supports generic concepts for types of analysis based on system execution behaviour, which may be represented at different levels of detail. Extra annotations needed for analysis are to be attached to an actual design model, rather than requiring a special version of the design model to be created only for the analysis. Even if the specification contains fine detail, the annotations may optionally be applied to aggregates. The same arguments may be applied to modeling software or embedded devices.

The core of the GQAM domain is the description of how the system behaviour uses resources.

Quantitative analysis techniques determine the values of "output NFPs" (such as response times, deadline failures, resource utilizations and queue sizes) based on data provided as "input NFPs" (e.g., request or trigger rates, execution demands, deadlines, QoS targets). The goals of analysis may have varying degrees of generality:

- A point evaluation of the output NFPs gives their values, along with decisions such as pass/fail.
- Sensitivity or scalability analysis is parameterized over variations in the input NFPs. It may seek to find which cases are satisfactory, and which are not; or to find the sensitivity of some measures to parameters which are not well determined.
- Some analysis may search over input NFP values to find feasible or optimal values.

The same NFP may be an input or output, depending on the context. For example a worst-case latency may be an output in WCET analysis, or an input in Schedulability Analysis.

Although NFPs may describe all aspects of a system (including, for example, heat generation and power consumption), this discussion centers on time and resource-related properties.

Time-Related NFPs

The core purpose of real-time analysis is to estimate the capability of a system to provide timely responses to requests for (or initiations of) specified system-level operations, which we will call services, and to handle an adequate frequency of requests, under specified conditions. To enable this analysis, a UML model must specify the system-level operations, the frequency of requests, and the conditions of execution (which we may term its environment).

Timeliness of a response can be defined in several different ways, as a property of the response delay to complete it. A recent survey is given by Sha et al. Some examples of definitions given in this survey are:

- Hard deadline: the response must be complete within this delay,
- Soft deadline: a stated percentage of responses must be complete within this delay. Quality-of-service specifications often are stated in these terms (see e.g. Jin and Nahrstedt, esp. Fig 4.).
- Delay cost function: a function of delay should be within a target value, or should be minimized. This is useful for trading off delays of multiple streams of requests that compete for resources. (see e.g. Franaszek and Nelson).
- Other statistical measures: the average delay, or the average of some function of some measure, must be within a target value, or some other measure must meet some requirement. The following real example is a generalization of soft deadlines: "the probability distribution function of delay must lie above a specified distribution function, so at each delay value the probability is higher than the specification".

The expression of such measures in service level agreements was discussed and surveyed recently by Skene et al. They point out the value of analysis of the execution path of the software.

Other NFPs

Although this chapter is concerned with time, it is instructive to consider others, such as memory and power usage (reliability and security are further examples not considered here).

Memory usage is determined by the size of objects that must be stored. As seen at the level of a system specification, these objects include:

- Executables when loaded.
- Data structures in memory, both static and dynamic. For dynamic data structures, the maximum size seems to be of the greatest interest. However a situation might arise where the program creates one buffer pool at one stage, then destroys it and creates another one at a later stage. A full analysis would then have to look at the memory use over the duration of a response, attaching sizes for a given object to particular operations. An example of a potentially dynamic data structure is a buffer pool.
- Messages sent between entities.
- Files.

Additional objects arise in the environment, including the operating system executable and data, file system cache and other memory objects, and the "heap".

Power use depends on the system configuration and deployment and on its behaviour, in that power is used to operate peripherals and memory, as well as to execute instructions and i/o operations. Power may be managed dynamically by a power control policy of the operating system, which responds to demands and battery status.

Power is related to time to execute a behavior, because the power used by a host processor is controlled through its clock speed, which affects its rate of operation.

Power management also applies to DRAM memories. (see "Memory Controller Policies for DRAM Power Management", Xiaobo Fan, Carla S. Ellis, Alvin R. Lebeck, Proceedings of the International Symposium on Low Power Electronics and Design (ISLPED), pages 129--134, August 2001).

:In wireless networks the power of transmission may be controlled, affecting messaging speed. Optimal policies take into account competition between nodes (see e.g. Cruz and Santhanam).

15.2 Domain view

Figures 15-2 to show the domain model for generic quantitative model-based analysis composed of four packages: GQAM, GQAM_Workload, GQAM_Observers and GQAM_Resources.

15.2.1 The GQAM package

The top-level GQAM package shown in Figure 15.2, is organized around the concept of AnalysisContext, which represents the root of the domain model. It contains two parts that address different concerns:

- WorkloadBehaviour (refined in Figure 15.3) contains a set of related end-to-end system-level operations, each with a defined behaviour, triggered over time as defined by a set of workload events.
- ResourcesPlatform (refined in Figure 15.5) is a logical container for the resources used by the system-level behaviour represented in the previous model.

AnalysisContext may have parameters of type VSL::Expressions::Variables, which define different cases being considered for analysis, and may affect the parameters of behaviour and resources (such as the number of repetitions of a sub-operation, or the size of a list).

Figure 15.2 - Top package of the GQAM domain model

15.2.2 The GQAM_Workload package

The package GQAM_Workload (Figure 15.3) describes workload and behaviour concerns. WorkloadBehaviour is a container for one or more end-to-end system operations (behaviours) used for analysis, and one or more streams of request events.

15.2.2.1 Workload concepts

Different workloads may correspond to different situations, such as takeoff, in-flight and landing of an aircraft, or peak-load and average-load of an enterprise application. Each workload is represented by a stream of triggering events, WorkloadEvent. Such a stream may be generated in different ways:

- by a timed event,
- by a stated arrival pattern which includes a wide range of classic models of event streams,
- from an arrival-generating mechanism represented by a Workload Generator (which may be modeled as a state-machine). There may be multiple independent identical mechanisms generating the stream, the number is called its "population".
- or from a trace (Event Trace) stored in a file.

In practice, one of these options is used and the others are left undefined. The arrivalPattern alternatives are described in Appendix D, but they include the PeriodicPattern, often used for schedulability, the Open and Closed patterns often used for performance analysis, and some less regular patterns. EventTrace has attributes for location (the file location or URL), format (a description of the trace record format) and content (for the trace data itself).

Figure 15.3 - GQAM_Workload package of the GQAM domain model

15.2.2.2 Behavior Scenario concepts

The behaviour in response to a trigger event is described by a BehaviorScenario, which is composed of sub-operations called Steps, any one of which can be refined as another BehaviorScenario. A BehaviorScenario captures any system-level behaviour description or any operation in UML, and attaches resource usage to it. Resources are used in three different ways:

- Each primitive Step has a host processor used to execute the operation of the step.
- A Step implicitly uses an operating system process which is a SchedulableResource.

- A Step may be a specialized AcquireStep or ReleaseStep to acquire or release a Resource, particularly a logical Resource representing a software resource.

BehaviorScenarios and Steps may also use other kind of resources, such as power and memory. For this reason, BehaviorScenario inherits from ResourceUsage (described in Chapter 10), which links resources with concrete usage demands. A few concrete forms of usage are defined at this level of specification, such as: memory, CPU execution time, energy from a power supply and size of messages to be sent through a network.

GQAM models Scenarios which terminate, and assumes that they are triggered repeatedly by the WorkloadEvent stream.

The predecessor-successor relationship between Steps may be a simple sequence, or it may be:

- branch (one predecessor Step, multiple successor Steps, each with a probability of selecting that branch).
- merge (multiple predecessor Steps, one successor triggered by any predecessor).
- fork (one predecessor Step, multiple successor Steps, indicating that all successors are executed logically in parallel).
- join (multiple predecessor Steps, one successor triggered by all predecessors completing).

These are represented in the Figure by the types of connectorKind in PrecedenceRelation.

Steps and BehaviorScenarios have quantitative attributes as shown in the Figure and described in Table 1 below. A Step can be optional (with a probability less than one of being executed), or repeated (with a repetition count). It can be refined as another BehaviorScenario (its "behavior" association). The "isAtomic" property specifies atomicity of execution (default is false).

A Step has a host association, a process (a SchedulableResource), and a hostDemand for its own execution time, which can be represented either as a time, or a number of operations on the host processor. It also may have optional requests (servDemand, with mean count servCount) for services from system components. To support demands for multiple services, these are expressed as ordered sets of service requests and counts, with the order corresponding one to the other.

A CommunicationStep defines the conveyance of a message between system entities, and has an attribute of the message size. The repetitions attribute of a CommunicationStep Inherited from Step) denotes multiple sendings (event multiplication) if >1, or decimation of sendings (event division) if <1. If repetitions is deterministic and less than 1 it is interpreted as event division by $N = 1/\text{repetitions}$, rounded to the nearest integer. That is, every Nth execution of the sending Step causes on cal to occur. Repetitions may also be a random quantity.

BehaviorScenarios in similar forms are widely used for timing analysis. In schedulability analysis they are called "task sequences" (Jane Liu, "Real Time Systems"), and specifications of timing normally refer to certain scenarios. Performance models are also created from scenarios (see e.g., Smith and Williams, "Performance Solutions"). Early analysis may be deliberately restricted to certain behaviours for certain triggers.

A BehaviorScenario may be represented by a UML interaction, statechart or activity diagram.

Time Intervals

Time intervals are defined by events that associated with units of behaviour, particularly Steps and BehaviorScenario, or with pairs of events from other sources. The inter-occurrence time interval between two between successive initiations of a behavior unit (the "interOccTime" NFP in Table 1-1 below) is one such example.

It is also sometimes necessary to define an interval between two events that are associated with separate units of behaviour, such as the interval between corresponding events on two parallel paths, to give the amount by which one parallel path leads or follows another.

Services

Services are provided by resources and by subsystems. A service by a subsystem is identified as a `RequestedService`, a subtype of `Step`. It is associated with an operation included in some interface of a system component, and is defined for analysis purposes as a `Step` refined by the `BehaviorScenario` for the behaviour of that operation.

15.2.3 GQAM_Observers Package

`TimedObservers` (Figure 15.4) are conceptual entities that define requirements and predictions for measures defined on an interval between a pair of user-defined observed events, named `startObs` and `endObs` in the figure. A `TimedObserver` must be extended to define the measure that it collects. The `LatencyObserver` makes this extension to collect the duration between the two events, and some properties of that duration. Other extensions can be defined to describe power or energy usage, memory usage, etc., over a partial behavior.

A `TimedObserver` uses `Timed Instant Observations` (from the `Time` subprofile) to define the start and end events in a given behavioral model. It may express constraints on the defined measure, for instance on the duration between the two time observations. It can use predefined and parameterized patterns (e.g., latency, jitter) or more elaborate expressions (e.g., written in OCL or VSL) since `TimedObserver` inherits all the modeling capabilities from `NfpConstraint`.

A `TimedObserver` may be attached to particular start and end observed events, or to a behavior element such as a `Step`. In the latter case the start and end events are the start and end events for execution of the behavior element.

`LatencyObserver` specifies a duration observation between `startObs` and `endObs`, with a miss ratio assertion (percentage), a utility function which places a value on the duration, and a jitter constraint. Jitter is the difference between the maximum and minimum duration.

Figure 15.4 - The GQAM Observers package

15.2.4 The GQAM_Resource Package

The top class in the GQAM_Resource package (Figure 15.5) is ResourcesPlatform, which represents a logical container for all the resources used to perform the behaviours described in the previous package.

Resources in real-time systems take a variety of forms, including hardware devices, software servers and logical resources like locks. The viewpoint of resources in Figure 15.5 is inherited from the GRM package: an abstract Resource class, with features shared by all resources which include a scheduling discipline, and a multiplicity called "resMult" for "maximum resource instances". In use it will also have an output NFP of resource utilization (for a multiple resource this is defined as the mean number of busy units), and for throughput (the number of requests handled successfully per unit time). A multiprocessor may be modelled as a single resource with multiple units and one scheduler (for a processor pool), or a collection of single resources each representing one processor, (where tasks are allocated to processors separately).

From an analysis viewpoint, these four types of resources shown in Figure 15.5 are important:

- ExecutionHost: a processor or other device that executes operations specified in the model. It has a host role relative to the processes and the Steps that execute on it.
- CommunicationsHost: hardware links between devices, with the role of host to the conveyance of a message.
- SchedulableResource: a schedulable service like a process or thread pool, which is a software resource managed by the OS.
- CommunicationChannel : a middleware or protocol layer that conveys messages.

There are also other concurrency resources, such as mutual exclusion resources (from the GRM chapter), which may be any mechanism which can make a program wait for a condition to be satisfied. Examples include a critical section, semaphores and locks; a finite buffer pool (a multiple resource, with multiplicity equal to the number of units of memory in the pool), or a pool of admission control tokens.

All resources have a scheduling discipline, a multiplicity (number of units of the resource), and offer Services. Explicit resource acquisition and release is mostly required for logical Resources, but for generality it is expressed in Figure 15-3 for any resource.

Resource usage by the software may cover an entire BehaviorScenario, or a few Steps. A Step runs on a processor which is its host, which is implicit in the deployment of the software component of which it is part, and it has a host demand which is its CPU requirement.

Figure 15.5 - GQAM_resources package of the GQAM domain model

Acquisition and release are operations which occur during the BehaviorScenario; they may be implicit in the behaviour. For instance, when a message goes to a process or thread, a thread/process resource must be acquired, or the scenario will block. Similarly, where a behavior scenario enters or leaves a critical section, the corresponding logical resource is acquired or released implicitly. Other logical resources, such as a locks, buffers, and admission tokens, are explicitly

acquired or released. Notice that the resource is different from the resource manager, which may be a process that implements the resource scheduler and has its own host and demands. The operation of an embedded system may have resources whose function depends on other resources.

Messages between processes that are not co-located use the links between their host processors; the links can often be identified implicitly from the deployment.

15.2.5 Common NFP Attributes for Analysis

There are several widely-used measures used for real-time requirements, parameters which are inputs to an analysis, and results which are outputs from it, including:

- Repetition count for a Step or a loop (repetitions).
- Probability of a subpath (probability).
- Host demand (CPU requirement) in time units (hostDemand).
- Host demand in host operations (hostDemandOps).
- Priority on the host (priority).
- Delay (including initial scheduling delay) (respTime).
- Delay (without initial scheduling delay) (executionTime).
- Time interval between two successive occurrences (interOccTime).
- Throughput (executions per unit time) (throughput).
- Utilization of the entity, meaning the fraction of time it is busy or (if it is reentrant or has multiple copies) the mean number of busy copies (utilization).
- Host utilization by the entity, the fraction of time its host is busy executing it (required and evaluated). (utilizationOnHost).

These quantities may be applied to different kinds of entities, as described in the following table.. All are optional, and may be an array of values.

Table 15.1 - Common NFP Attributes for Analysis

NFP	For Resource	For Scenario and Step	For WorkloadEvent
repetitions: NFP_Real[*]	repetitions, N/A	the number of times the Step is repeated, once triggered (default = 1).	N/A
probability: NFP_Real[*]	probability, N/A	the probability that the step is executed, following its predecessor (for conditions)	N/A
hostDemand: NFP_Duration[*], hostDemandOps:NFP_Real[*]	composite demand across all services of the Resource, in terms of time and in terms of processor operations	For a Step, the CPU demand on the host of the process that executes the Step. For a Scenario, the sum of all demands for all its Steps.	N/A

Table 15.1 - Common NFP Attributes for Analysis

priority : NFP_Integer[*]	N/A	For a Step, priority on its host	N/A
respTime: NFP_Duration[*]	response time, composite average response time across all services offered by the resource	total delay from the trigger event until completion of the Step or Scenario	required value for the Scenario
execTime : NFP_Duration[*]	execution time, N/A (same as hostDemand)	respT minus any initial scheduling delays	N/A
interOccTime: NFP_Duration[*]	inter-occurrence time, interval between successive requests for services	interval between initiations	interval between trigger events
throughput : NFP_Frequency[*]	frequency of requests for all services	frequency of initiations	frequency of the trigger event
utilization : NFP_Real[*]	fraction of time the resource is active (has an active service). For a multiple resource, the mean number of busy units.	fraction of time the BehaviorScenario is active (between its trigger event and its completion)	N/A
utilizationOnHost: NFP_Real[*]	N/A	fraction of time the host is busy executing the BehaviorScenario. If it has multiple hosts, this is a set of values.	N/A
blockingTime: NFP_Duration[*]	blocking time, N/A	a pure delay waiting for passive resources to be available or an event controlled from elsewhere (value is an output variable)	N/A
selfDelay: NFP_Duration[*]	delay	a pure delay controlled or requested by the Step. (value is an input variable)	N/A

For a BehaviorScenario, which is a composite entity, some NFPs apply directly (repetitions, probability, response time, inter-occurrence time and throughput) while others either do not apply or represent sums of the attributes of the Steps that make up the Scenario, weighted by their throughputs relative to that of the BehaviorScenario (execution time, hostDemand, utilizationOnHost).

15.3 UML Representation

15.3.1 Profile Diagrams

The UML extensions for the GQAM sub-profile are presented in this section. The sub-profile is split in four figures related to corresponding domain model packages GQAM, GQAM_Workload, GQAM_Behavior, GQAM_Observers, and GQAM_Resources.

In general, resource-related stereotypes extend the UML metaclass Classifier. More exactly, the stereotypes GaExecHost, GaCommHost and GaCommChannel specialize the stereotype GRM::Resource, defined in the GRM chapter (10.3.2.12, p. 117), which extends in turn Classifier, InstanceSpecification and Property (the last used for annotating Parts in UML composite structure diagrams). Therefore, resource stereotypes can be applied to all kinds of classes, instances, components, parts and deployment nodes.

GaScenario and Step stereotypes inherit from TimeModels::TimedProcessing (which extends Behavior, Message, Actions) and GRM::Resource (which extends NamedElement). So, Scenario and Step stereotypes can be applied to a wide set of behavior-related elements covered by the UML2 metaclass NamedElement, such as Operations, Actions, Messages that initiate Operations or Actions, Transitions and States in state machine diagrams, Signals that trigger state machine transitions, Events, ExecutionOccurrenceSpecifications and InteractionFragments in interaction diagrams, InputPins in activity diagrams and UseCases.

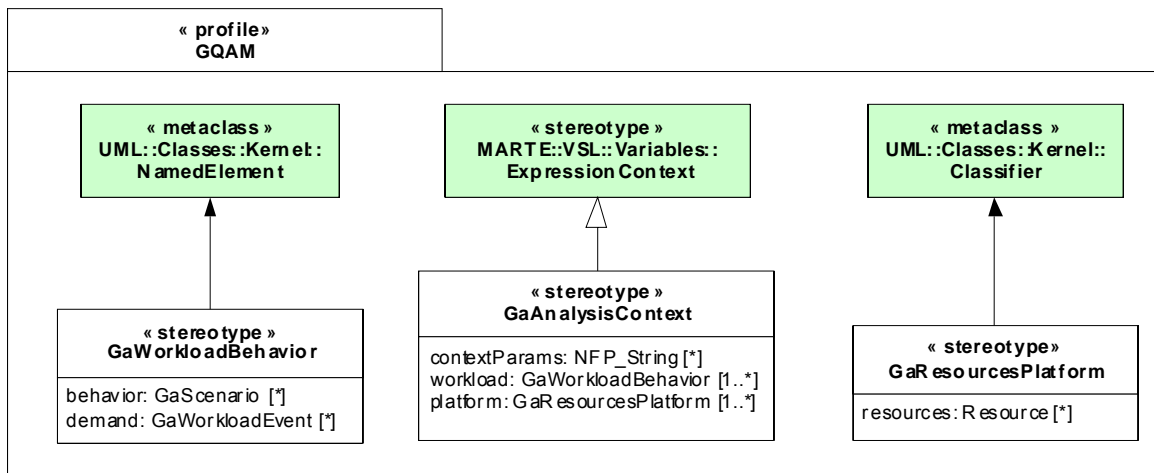

Figure 15.6 - UML extensions for top level stereotypes of the GQAM profile

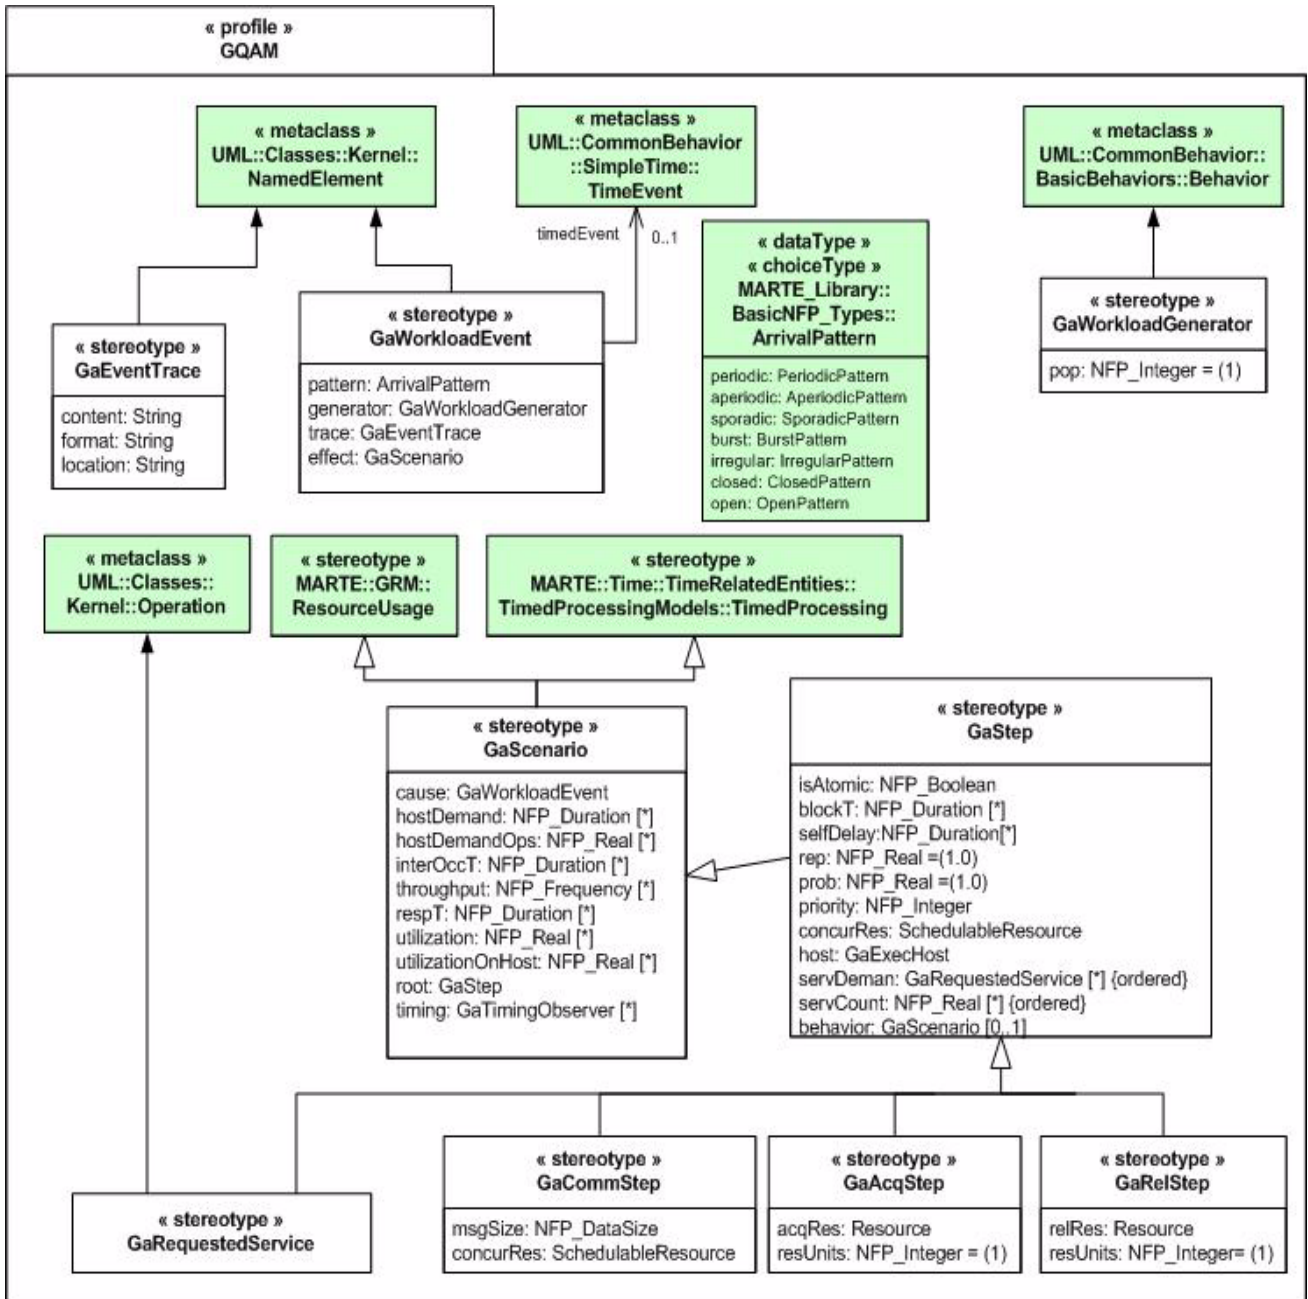

Figure 15.7 - UML extensions for GQAM stereotypes related to behavior

Figure 15.8 - GQAM stereotype for observing timing occurrences between two events

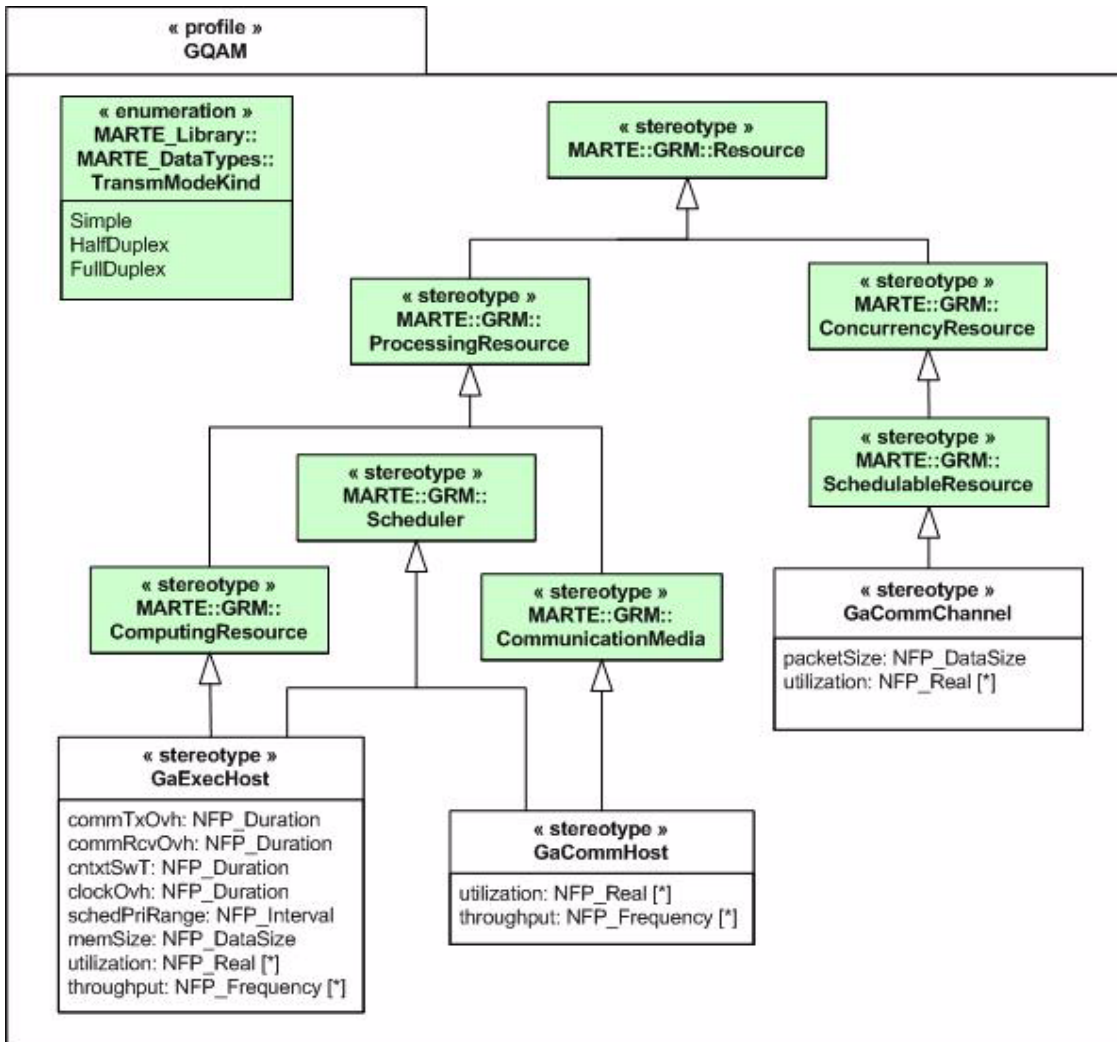

Figure 15.9 - UML extensions for GQAM stereotypes related to resources

15.3.2 Profile Elements Description

In this section are described the stereotypes of the GQRM profile (listed in alphabetical order).

15.3.2.1 GaAcqStep

The GaAcqStep stereotype maps the AcquireStep domain element (section F.10.1, p. 537) denoted in Annex F.

A step that acquires a resource.

Extensions

- None.

Generalizations

- GaStep.

Associations

- None.

Attributes

- acqRes: Resource [0..1] the resource to be acquired within the step execution.
- resUnits : NFP_Integer [0..1]= 1 the number of units of resource acquired within the step execution.

Constraints

- None.

15.3.2.2 GaAnalysisContext

The GaAnalysisContext stereotype maps the AnalysisContext domain element (section F.10.2, p. 537) denoted in Annex F.

For a given analysis, the context identifies the model elements (diagrams) of interest and specifies global parameters of the analysis.

Extensions

- None.

Generalizations

- ExpressionContext (from MARTE::VSL::Expressions).

Associations

- None.

Attributes

- contextParams: NFP_String [*]
 a set of annotation variables defining global properties of this analysis context.

Constraints

- None.

15.3.2.3 GaCommChannel

The GaCommChannel stereotype maps the CommunicationChannel domain element (section F.10.4, p. 538) denoted in Annex F.

It is used for denoting a logical communications layer connecting SchedulableResources.

Extensions

- None.

Generalizations

- SchedulableResource (from MARTE::GRM).

Associations

- None.

Attributes

- packetSize: NFP_DataSize [0..1] the size of the data unit handled by the channel.

Constraints

- None.

15.3.2.4 GaCommHost

The GaCommHost stereotype maps the CommunicationHost domain element (section F.10.5, p. 539) denoted in Annex F. It is used for denoting a physical communications link.

Extensions

- None.

Generalizations

- CommunicationMedia (from MARTE::GRM).
- Scheduler (from MARTE::GRM).

Associations

- None.

Attributes

- throughput: NFP_Frequency [*] actual throughput.
- utilization: NFP_Real [*] utilization of this host.

Constraints

[1] The associations processingUnits and mainScheduler inherited from Scheduler and ProcessingResource respectively have as default values the very same element that is being annotated with the GaCommHost stereotype.

15.3.2.5 GaCommStep

The GaCommStep stereotype maps the CommunicationStep domain element (section F.10.6, p. 539) denoted in Annex F. A CommStep is an operation which conveys a message from one locale to another.

Extensions

- None.

Generalizations

- GaStep

Associations

- None

Attributes

- msgSize: NFP_Datasize [*] the size of the message.

Constraints

- None

15.3.2.6 GaEventTrace

The GaEventTrace stereotype maps the EventTrace domain element (section F.10.7, p. 539) denoted in Annex F. A trace of events that can serve as source for the request event stream.

Extensions

- NamedElement (from UML::Classes::Kernel)

Generalizations

- None.

Associations

- stream: GaWorkloadEvent the event stream driven by the trace

Attributes

- content: String [0..1] contains the serialization of the event trace according to the file format.
- format: String [0..1] this indicates the format of the event trace - which is how the string content should be interpreted.
- location: String [0..1] this contains a location that can be used by a tool to locate the file as an alternative to embedding it in the stereotype.

Constraints

- None.

15.3.2.7 GaExecHost

The GaExecHost stereotype maps the ExecutionHost domain element (section F.10.4, p. 538) denoted in Annex F. It denotes a processor which executes Steps.

Extensions

Generalizations

- ComputingResource (from MARTE::GRM).
- Scheduler (from MARTE::GRM).

Associations

- None.

Attributes

- commTxOvh: NFP_Duration [*] the host demand for sending messages.
- commRcvOvh:NFP_Duration [*] the host demand for receiving messages.
- cntxtSwT: NFP_Duration [*] context switch time.
- clockOvh: NFP_Duration [*] clock overhead.
- schedPriRange: NFP_Interval [*] the range of priorities offered by this processor.
- memSize: NFP_DataSize [0..1] the memory size.
- utilization: NFP_Real [*] the processor utilization, expressed as mean busy processors (in the range from 0 to resMult which is the number of processors).
- throughput: NFP_Frequency [*] the throughput of the host in scheduled initiations/sec.

Constraints

[1] The associations processingUnits and mainScheduler inherited from Scheduler and ProcessingResource respectively have as default values the very same element that is being annotated with the GaExecHost stereotype.

15.3.2.8 GaLatencyObs

The GaLatencyObs stereotype maps the LatencyObserver domain element (section F.10.10, p. 540) denoted in Annex F. GaLatencyObs specifies a duration observation between startObs and endObs UML TimeObservations, with a miss ratio assertion (percentage), a utility function, which places a value on the duration, and a jitter constraint. Jitter is the difference between maximum and minimum duration.

Extensions

- None

Generalizations

- GaTimedObs

Attributes

- latency: NFP_Duration [*]
value of the latency.
- miss: NFP_Real [*]

for soft timing constraints the miss ratio indicates the admitted or actual percentages of "required" latency missed.

- utility: UtilityType [0..1]
value of importance for required timing constraints.
- maxJitter: NFP_Duration [*]
maximum deviation value. It represents a maximum deviation with which a periodic internal event is generated. The output jitter is calculated as the difference between a worst-case latency time and the best-case latency time for the observed event measured from a reference event.

Constraints

- None

15.3.2.9 GaRelStep

The GaRelStep stereotype maps the ReleaseStep domain element (section F.10.13) denoted in Annex F.

It denotes a step that releases a resource.

Extensions

- None

Generalizations

- GaStep

Associations

- None

Attributes

- relRes:Resource [0..1] the resource to be released.
- resUnits : NFP_Integer [0..1] = 1 how many units to be released (default = 1).

Constraints

- None.

15.3.2.10 GaResourcesPlatform

The GaResourcesPlatform stereotype maps the ResourcesPlatform domain element (section F.10.16) denoted in Annex F.

A logical container for the resources used in an analysis context.

Extensions

- Classifier (from UML::Classes::Kernel)

Generalizations

- None

Associations

- None

Attributes

- resources: Resource[*] set of resources contained by this container.

Constraints

- None

15.3.2.11 GaRequestedService

The GaRequestedService stereotype maps the RequestedService domain element (section F.10.15) denoted in Annex F.

A request for an operation by some system object, for instance a subsystem defined by component notation and interface operations. The operation details may be defined by a Scenario attached by the behavior association inherited from Step.

Extensions

- Operation (from UML::Classes::Kernel).

Generalizations

- GaStep

Associations

- None

Attributes

- None

Constraints

- None

15.3.2.12 GaScenario

The GaScenario stereotype maps the BehaviorScenario domain element (section F.10.3) denoted in Annex F.

A Scenario captures system-level behaviour and attaches allocations and resource usages to it. It is composed of sub-operations called Steps, any one of which can be a composite Step, refined as another Scenario.

Extensions

- None

Generalizations

- ResourceUsage (from MARTE::GRM)

- TimedProcessing (from MARTE::Time::TimeRelatedEntities::TimedProcessingModels)

Associations

- steps: Step [1..*]
the set of steps that make up the Scenario.

Attributes

- hostDemand: NFP_Duration [*]
the cpu demand in units of time, if all Steps are on the same host.
- hostDemandOps: NFP_Integer [*]
the cpu demand in units of operations, if all Steps are on the same host.
- interOccT: NFP_Duration[*]
the interval between successive initiations of the scenario.
- throughput: NFP_Frequency[*]
the mean rate of initiation of the scenario.
- respT: NFP_Duration[*]
the time duration from initiation to completion, for one execution of the scenario.
- utilization: NFP_Real[*]
the occupancy of the scenario, computed as the mean number of scenario instances active at any one time.
- utilizationOnHost: NFP_Real[*]
the occupancy of the host processor, executing Steps of this scenario, if all Steps are on the same host.
- root: GaStep [0..1]
the first Step of the scenario.

Constraints

- [1] The hostDemand and hostDemandOps attributes derive their values from the Steps in the Scenario, but only in cases where all the Steps have the same Host.

15.3.2.13 GaStep

The GaStep stereotype maps the Step domain element (section F.10.17) denoted in Annex F.

A GaStep is a part of a Scenario, defined in sequence with other actions, and may be a composite Step containing a Scenario

The precedence relations in the domain model are not defined as associations because they do not need to be explicitly defined in the UML behavior, they are given implicitly by the diagram.

Extensions

- None

Generalizations

- GaScenario.

Associations

- behavior: GaScenario [0..1] a GaScenario which refines a composite Step.

Attributes

- isAtomic: NFP_Boolean [0..1] = false
if true, the step must not be decomposed any further.
- blockT: NFP_Duration [*]
a delay inserted in the execution of the Step, waiting for an event controlled elsewhere (by another step or scenario), or for a condition such as the availability of passive protected resources needed by the step but in use by preempted (i.e. lower priority schedulableResources) concurrent steps.
- selfDelay: NFP_Duration [*]
a delay inserted in a Step, whose duration is controlled or requested by the Step (e.g. a sleep time).
- rep: NFP_Real [*] = 1
the actual or average number of repetitions of an operation or loop.
- prob: NFP_Real [*] = 1
the probability of the step to be executed (for a conditional execution).
- priority: NFP_Integer [0..1]
the step priority on its host processor.
- concurRes: GrmSchedulableResource [0..1]
the process which executes the Step.
- host: GaExecHost [0..1]
the host processor
- servDemand: GaRequestedService [*] {ordered}
a set of operations requested by the Step, such as calls to interface operations. The order corresponds to the order in servCount.
- servCount: NFP_Real [*] {ordered}
a set of values for the number of requests to the operations given in the list for GaRequestedService, in the same order.

Constraints

[1] the elements of the ordered lists servDemand and servCount correspond, element to element.

[2] a composite Step (with the behavior association defined) cannot have a host or concur association.

15.3.2.14 GaTimedObs

The GaTimedObs stereotype maps the TimedObserver domain element (section F.10.18) denoted in Annex F.

GaTimedObs is a purely conceptual entity that serves to collect timing requirements and predictions that relates to user-defined observed events. In this sense, GaTimedObs uses UML TimeObservations to define the observed event in a given behavioral model.

Extensions

- None.

Generalizations

- NfpConstraint (from NFPs::NFP_Annotation)

Associations

- endEvent: Time::TimedRelatedEntities::TimedObservations::TimedInstantObservation [0..*]
observed event to which the timing observer apply.
- startEvent: Time::TimedRelatedEntities::TimedObservations::TimedInstantObservation [0..*]
reference event.

Attributes

- laxity: LaxityKind [0..1]
indicates whether required timing constraints are hard or soft.

Constraints

- None

15.3.2.15 GaWorkloadBehaviour

The GaWorkloadBehaviour stereotype maps the WorkloadBehavior domain element (section F.10.18, p. 544) denoted in Annex F.

A logical container for the analyzed behavior and the workload that triggers it, in an analysis context.

Extensions

- NamedElement (from UML::Classes::Kernel).

Generalizations

- None

Associations

- None

Attributes

- behavior: GaScenario [*]
- demand: GaWorkloadEvent [*]

Constraints

- None

15.3.2.16 GaWorkloadEvent

The GaWorkloadEvent stereotype maps the WorkloadEvent domain element (section F.10.20) denoted in Annex F.

A stream of events that initiate system-level behaviour. It may be generated in different ways: by a stated arrival process (such as Poisson or deterministic), by an arrival-generating mechanism modeled by a workload generator class, by a timed event and from a trace.

Extensions

- NamedElement (from UML::Classes::Kernel)

Generalizations

- None

Attributes

- pattern: MARTE::MARTE_Library::BasicNFP_Types::ArrivalPattern [0..1]
if defined, this attribute defines a pattern of arrival events.
- generator: GaWorkloadGenerator [0..1]
a workload generator that produces the events
- trace: GaEventTrace [0..1]
indicates an event trace file
- timeEvent: UML::CommonBehaviors::SimpleTime::TimeEvent [0..1]
a time event in the UML specification that triggers the request events.

Associations

- None

Constraint

[1] Only one of the four attributes may be defined.

15.3.2.17 GaWorkloadGenerator

The GaWorkloadGenerator stereotype maps the WorkloadGenerator domain element (section F) denoted in Annex F.

A mechanism defined by a UML behavior definition such as a state machine, that generates events to drive the system behavior, for example by invoking a top-level system behavior (scenario). There may be multiple independent and identical instances (population > 1).

Extensions

- Behavior (from UML::CommonBehavior::BasicBehavior).

Generalizations

- None

Associations

- None

Attributes

- pop: NFP_Integer [0..1] = 1

Constraints

- None

15.3.2.18 LaxityKind

The LaxityKind is an Enumeration that includes a list of qualifiers specifying the criticality of a given 'required' timing property.

Enumeration literals

- hard the required timing specifications have to be met for system behavior correctness.
- soft if the required timing specifications are not met the system behavior is still correct. Further specifications, such as the miss ratio, can be used to specify the limit of timing misses.
- other a user-specific laxity.

16 Schedulability Analysis Modeling

16.1 Overview

In this chapter, we describe a component of the MARTE profile that is intended specifically for schedulability analysis. As it is known, when dealing with real-time systems, the influence of scheduling on the timing and performance is crucial to calculate guaranteed bounds on responses times and resource processing loads. The maturity of scheduling analysis techniques has led to a set of useful mathematical formalisms like the classic and generalized Rate Monotonic Analysis (RMA), holistic techniques, or extended timed automata.

Typical tools for this class of model analysis provide two important functions:

- The first one is to calculate the schedulability of the system or a particular piece of software; that is, the ability of the system to meet certain temporal constraints (e.g., deadlines, miss ratios) defined for the entire system or for a group of individual concurrent execution units. Such tools typically indicate which entities are schedulable and which are not.
- Sensitivity analysis assists with determining how the system can be improved. That may mean suggestions for making an entity schedulable or it may mean epitomizing system usage for a more balanced system. A system designer will typically want to analyze the system under several configurations using different parameter values for each scenario, or to explore the variability of different resource allocations and deployment into alternative hardware and software platforms.

Schedulability analysis can be used at different stages. Early analysis of a design model aids developers to detect potentially unfeasible real-time architectures and prevents costly design mistakes, particularly related to timing behavior. On the other hand, a later analysis of an implemented system allows analyzers to discover (with more precise quantitative information of the system) temporal-related faults, or to evaluate the impact of possible platform migrations or modifications on the scheduling strategies.

This chapter describes a set of common annotations for model-based schedulability analysis. It allows quantitative annotations to be attached at the level of detail desired by the designer. Indeed, even if the specification might contain extreme detail, the set of annotations may optionally be partially applied. On the other hand, each vendor is encouraged to supply specialized profiles that extend this set in order to perform model analysis that is more extensive.

It was actually stated that the SPT's sub-profiles for schedulability and performance analysis were too much independently defined, reducing the ability to reuse annotated models for any kind of analysis. To improve this aspect, we introduced a common framework, named Generic Quantitative Analysis Modeling (GQAM), supporting both kinds of timing analysis. The modeling framework described in this section attempts to specialize GQAM into a collection of modeling concepts for model-based schedulability analysis purposes, as well as a set of Non-Functional Properties (NFPs) for these basic concepts. This framework therefore involves the use of the NFP Modeling framework presented in chapter 8.

The structure of this section follows the convention adopted throughout this document: First, a domain viewpoint is described that identifies the basic abstractions used in schedulability analyses. The semantics of these abstractions and their relationships are explained with the aid of metamodels. The second part of the chapter describes how these abstractions are expressed in the UML metamodel. This is done through a series of UML extensions (stereotypes, constraints, and tag definitions).

Supplementing this description is a set of illustrative examples showing common ways of applying this part of the MARTE profile.

16.2 Domain View

The Schedulability Analysis Modeling (SAM in short) domain model uses similar domain concepts as those presented in the GQAM framework. Since these concepts are already described in a general way, we define here their semantics in the schedulability analysis domain and add the NFPs used for these purposes. All the NFP data types for schedulability analysis

are declared in a model library (the BasicNFP_Types model library is presented in Annex D).

The SAM sub-profile has many facets that are grouped in individual packages. The overall package structure is shown in Figure 16.1.

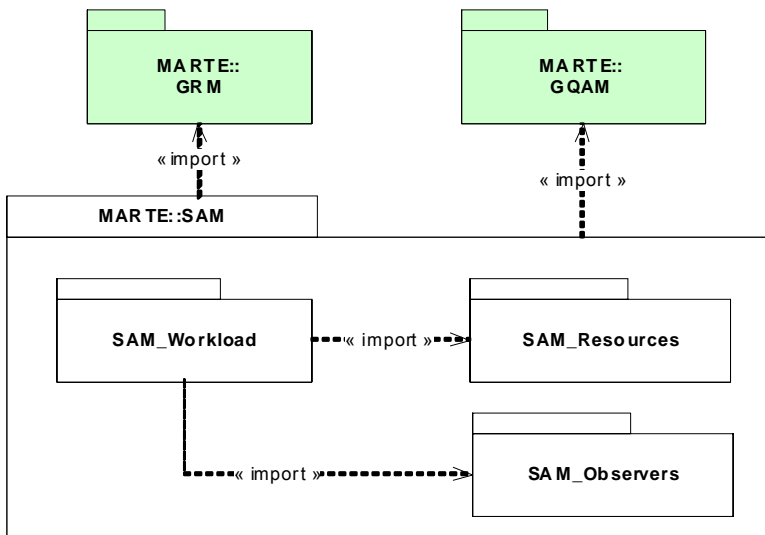

Figure 16.1 - Structure of the SAM domain model

The purpose and contents of each package are described in subsequent sections.

16.2.1 The SAM root package

As the GQAM chapter, the SAM's conceptual domain model is organized around the notion of Analysis Context (Figure 16.2). An analysis context is the root concept to collect relevant quantitative information for performing a specific analysis scenario. Starting with the analysis context and its elements, a tool can follow the links of the model to extract the information that it needs to perform the model analysis.

Analysis contexts are also known as real-time situations in the schedulability analysis domain. In particular, a SaAnalysisContext is a kind of AnalysisContext with additional attributes. The isSchedulable attribute indicates whether all the timing constraints defined for the analysis context are respected. The optimalityCriterion attribute denotes a global criterion used to determine a schedule for the context analyzed (e.g., meet all hard deadlines, minimize the number of missed deadlines, minimize the mean tardiness, maximize flow).

Note – Most of specialized SAM-specific concepts have the prefix "Sa", which stands for "Schedulability Analysis".

In general, AnalysisContext is associated with the following two modeling concerns:

- WorkloadBehavior: represents a given load of processing flows triggered by external (e.g., environmental events) or internal (e.g., a timer) stimuli. The processing flows are modeled as a set of related steps that contend for use of processing resources and other shared resources.
- ResourcesPlatform: represents a concrete architecture and capacity of hardware and software processing resources used in the context under consideration.

Figure 16.2 - The SAM root domain model: Analysis context

Since analysis models are intended to be integrated with existing design models, or at least to be defined in a separated view with a clear mapping to design views, we are especially interested on collecting modeling elements according to the abovementioned modeling concerns. Indeed, this separation of modeling concerns is essential to support the MDA approach. Splitting an analysis context model into these two aspects allows MDA modelers to keep platform-independent models (models annotated with WorkloadBehavior elements) separated from platform description models (ResourcesPlatform annotations). We illustrate an example supporting this approach in section 16.3.3, p.279. This feature attempts to enhance the modeling practices fostered by MARTE in order to ease retargetability of logical model elements onto execution platforms models possibly stored into reusable libraries (this is one of the key requirements of the MARTE RFP).

In the remaining subsections, we describe the main concepts related to these modeling concerns.

16.2.2 The SAM Workload package

The SAM_Workload package contains concepts related to the processing load on the system. We split this package in two figures (Figure 16.3 and Figure 16.4).

The end-to-end related concepts are gathered in Figure 16.3. This figure shows the constructs required to specify the end-to-end behavior and the associated quantitative information concerning end-to-end stimuli, timing requirements and responses.

Note: In general, most of the discussed concepts are imported from GQAM and GRM. For explanation purposes, we show here some available attributes of interest for schedulability analysis. For a complete list of attributes of the imported concepts, refer to the respective chapters.

In a given analysis context, a single WorkloadBehavior situation is commonly evaluated. A WorkloadBehavior situation may correspond to a mode of system operation (e.g. starting mode, fault recovering, or normal operation) or a level of intensity of environment events. A specific WorkloadBehavior model is defined by the set of end-to-end processing flows (EndToEndFlow), which represent the analyzed workload.

End-to-end flows describe a unit of processing work in the analyzed system, which contend for use of the processing resources. This is a conceptual entity only, which is represented by its concrete elements: end-to-end stimuli and end-to-end response.

Figure 16.3 - The SAM Workload domain model: EndToEndFlow (partial view)

End-to-end flows refer to a set of stimuli requesting computations. We may refer to an instance of a particular request stimulus as an event occurrence. Since the stimulus can occur repeatedly, we refer to recurrence of events as WorkloadEvent. Workload events can be originated outside the system, inside the system, or because of the passage of time. From a modeling viewpoint, workload events can be modeled by known patterns (see the definition of the ArrivalPattern data type in Annex D), by traces files, by internal timed event models, or by workload generator models (e.g., state machine models). Workload event models are fully defined in the GQAM chapter, page 244.

A computation that is performed as a consequence of a workload event is referred to as the behavior scenario (BehaviorScenario) that executes in response to its event occurrences. Depending on the implementation nature of behavior scenarios, they could be concretized in a single task executing in one processor or in dependent tasks into single or multiple processors. But ultimately, behavior scenarios serve to describe end-to-end responses of a workload model under analysis.

As a conceptual entity, end-to-end flow allows to define a set of timing requirements and timing predictions. Timing requirements include deadlines, maximum miss ratios and maximum jitters. Timing predictions are typically provided by analysis tools and include latencies, jitters, and other scheduling metrics. These aspects are modeled by the TimedObserver concept. Section 16.2.3 (p.268) provides details on this.

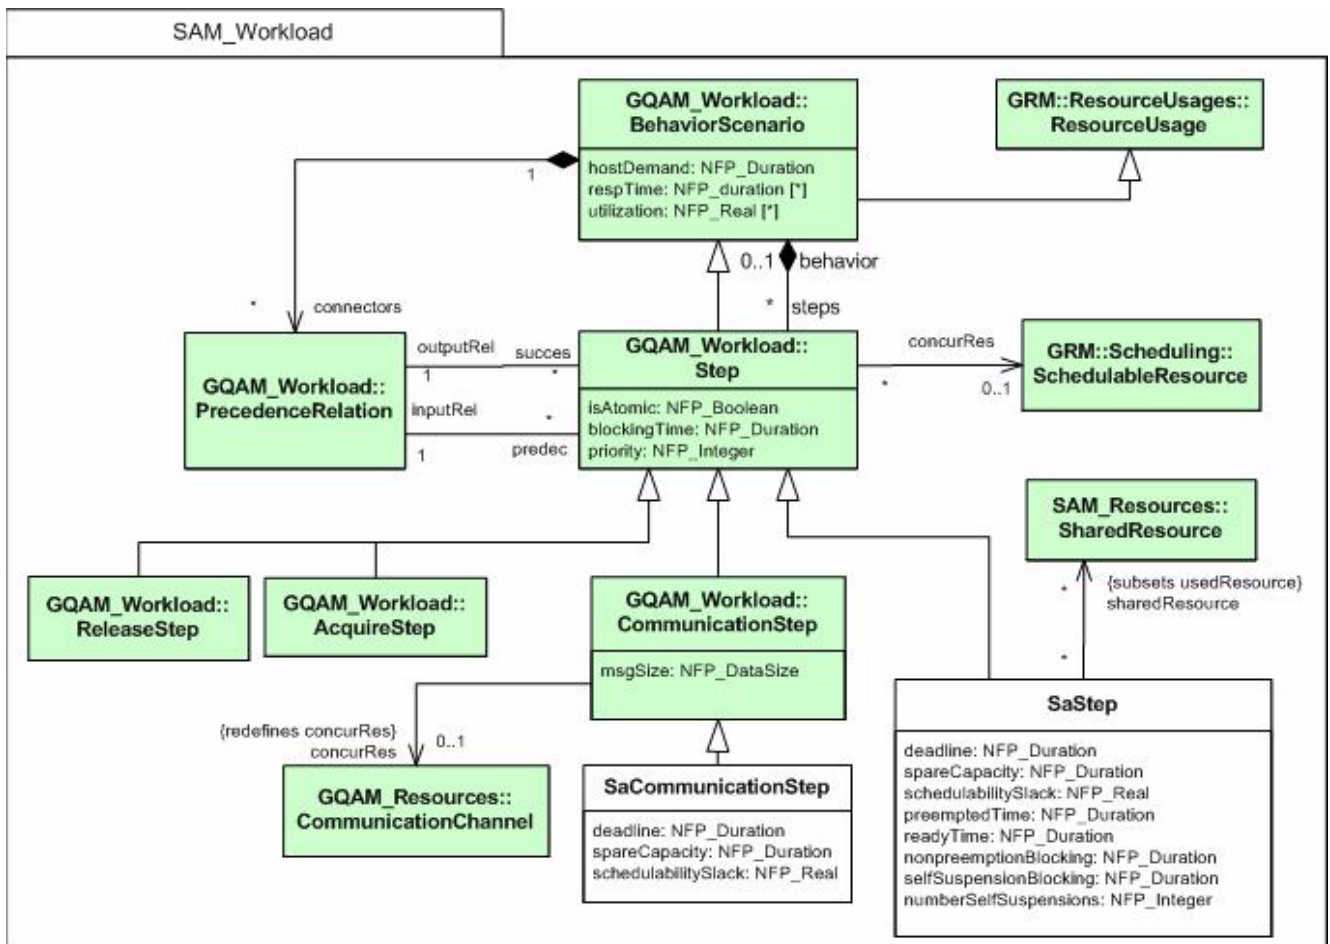

Figure 16.4 - The SAM Workload domain model: BehaviorScenario (partial view)

Additionally, end-to-end flows are characterized by a set of NFPs. `isSchedulable` indicates whether the flow meets all its deadlines. `schedulabilitySlack` provides a percentage measure by which the (effective) execution time of all the atomic processing units participating in the end-to-end response may be increased while still keeping the end-to-end flow schedulable. `EndToEndTime` and `EndToEndDeadline` are respectively the predicted worst completion time and required completion latency of the end-to-end response measured from the arrival of the requested event. This applies if only one input end-to-end stimuli exist and only one finalization Step exists.

Figure 16.4 shows the domain concepts for defining behavior execution modeling aspects. This model is based on the one introduced in the GQAM framework.

Thus, the BehaviorScenario concept serves to collect detailed descriptions of the response behavior. Depending on the implementation nature of BehaviorScenario, they could be concretized in a single step executing in one processor or in a number of flow related steps into single or multiple processors. A step may represent a small segment of code execution as well as the sending of a message through a communication media (ExecutionStep and CommunicationStep). The ordering of steps follows a predecessor-successor pattern, with the possibility of multiple concurrent successors and predecessors, stemming from concurrent thread joins and forks respectively. The granularity of a step is often a modeling choice that depends on the level of detail that is being considered. Hence, a step at one level of abstraction may be decomposed further

into a set of finer-grained steps.

Schedulability analysis models commonly restrict steps to processing units that must not change allocation of system resources. Scheduling-based processing steps (SaStep and SaCommunicationStep) begin and end when decisions about the allocation of system resources are made, as for example when changing its priority. As a main concept on schedulability analysis models, step deadlines define the maximal time bounds on the completion of particular segments that must be met. The SaStep concept is enriched with other latency properties such as preempted time and ready time. Notice that the association requiredAmount inherited from ResourceUsage (see Section 10.2.5) is used to model execution times. The worst, average, and best execution times are modeled with different instances of the usage attribute by means of the statistical qualifier slot in NFP types. For instance, a pair of worst and best case execution time values is: "execTime= {(5.0, ms, max),(3.0, ms, min)}". The same case applies for whatever attribute typed with a NFP data type.

In this model, steps use the active resource services for execution by means of schedulable resources (e.g., threads, process in execution resources) and communication channels (e.g., message management units) characterized by concrete scheduling parameters, and synchronize through calls to shared resources (for instance, I/O devices, DMA channels, critical sections or network adapters) identified using the sharedResource association of the SaStep instances.

16.2.3 The SAM Observers package

Timing Observers (Figure 16.5) are purely conceptual entities that serve to collect timing requirements and predictions that relates to user-defined observed events. In this sense, Timing Observer use Timed Instant Observations (chapter 9) to define the observed event in a given behavioral model. Timing observers are a powerful mechanism to annotate and compare timing constraints against timing predictions provided by analysis tools. Timing observers can be used as predefined and parameterized patterns (e.g., latency, jitters) or by means of more elaborated expressions since TimedObserver inherits all the modeling capabilities from NFP_Constraint.

Note that these modeling constructs are mainly useful for complex end-to-end flows with several observation points in order to provide centralized and flexible means to annotate analyzer-defined timing constraints. Most of analysis tools provide a repository to store this kind of global information that is more related with the exploration of constraint cases.

Timing observers are typically of two kinds in schedulability analysis: required and offered. Required timing observers represent timing constraints such as deadlines or required maximum jitters. Offered timing observers specify prediction results mostly calculated by analysis tools.

Two kinds of timing observer patterns are used in SAM. LatencyObserver specifies a duration observation with its corresponding miss ratio percentage assertion (percentage), a utility value of a latency value, and a maximum jitter with which a periodic internal event is generated. The output jitter is calculated as the difference between a worst-case latency time and the best-case latency time for the observed event measured from a reference event. Required latency values are known as deadlines in real-time systems. SchedulingObserver provides prediction about scheduling metrics such as overlaps, the maximum number of suspensions caused by shared resources or the blocking time caused by the used shared resources. All these metrics are relative to the interval defined by the reference and observed events.

Timing observers must be attached to behavior elements. When the reference and observed events are not defined, the start and finish events can be deduced from the behavior element annotated.

Figure 16.5 - The SAM Observers domain model

16.2.4 The SAM Resources package

In the SAM framework, the concept of resourcesPlatform matches to the engineering model of resources introduced in the SPT profile. That includes not only hardware resources (CPU, devices, backplane buses, network resources), but also software ones (threads, tasks, buffers). Figure 16.6 shows a framework to describe the platform of resources.

Schedulability models use an abstracted version of a more structured and detailed platform model (see chapter 14 for detailed resources models), which is especially useful for expressing NFPs oriented to quantitative analysis and without distinguishing among different abstraction levels (hardware, RTOS or middleware).

As defined in GQAM, the resources platform model consists of a set of resources with explicit NFPs. Specifically, throughput properties e.g., processing rate, efficiency properties e.g., utilization and overhead properties as for example blocking times and clock overhead times. This model distinguishes two kinds of processing resources: execution hosts (e.g., processors, coprocessors) and communication hosts (e.g. networks, buses). For each one, the SAM framework adds specialized NFPs. Particularly, schedulability metrics, interrupt overheads and utilization of scheduling processing.

Two kind of concurrent resources are used by steps to access processing hosts: schedulable resources and communication channels. SchedulableResource is a kind of active protected resource that is used to execute steps. In a RTOS, this is the mechanism that represents a unit of concurrent execution, such as a task, a process, or a thread. In a communication host, the related element is CommunicationChannel, which may be characterized by concrete scheduling parameters (like the packet size). Schedulable resources are scheduled with a chosen set of scheduling parameters associated to a given scheduling algorithm. The component that implements these algorithms is called the scheduler.

Schedulers can be of two types: system schedulers (typically a RTOS scheduler) that offer the whole processing capacity of its associated base processors to its allocated schedulable resources, and secondary schedulers that only provide the processing capacity offered by its hosting schedulable resource. This hierarchical structure is typically used in real-time systems when users are interested in applying dynamic scheduling on top of commercial RTOS supporting only static scheduling. Likewise,

novel algorithms exist that allow to perform real-time analysis of these hierarchical configurations of schedulers.

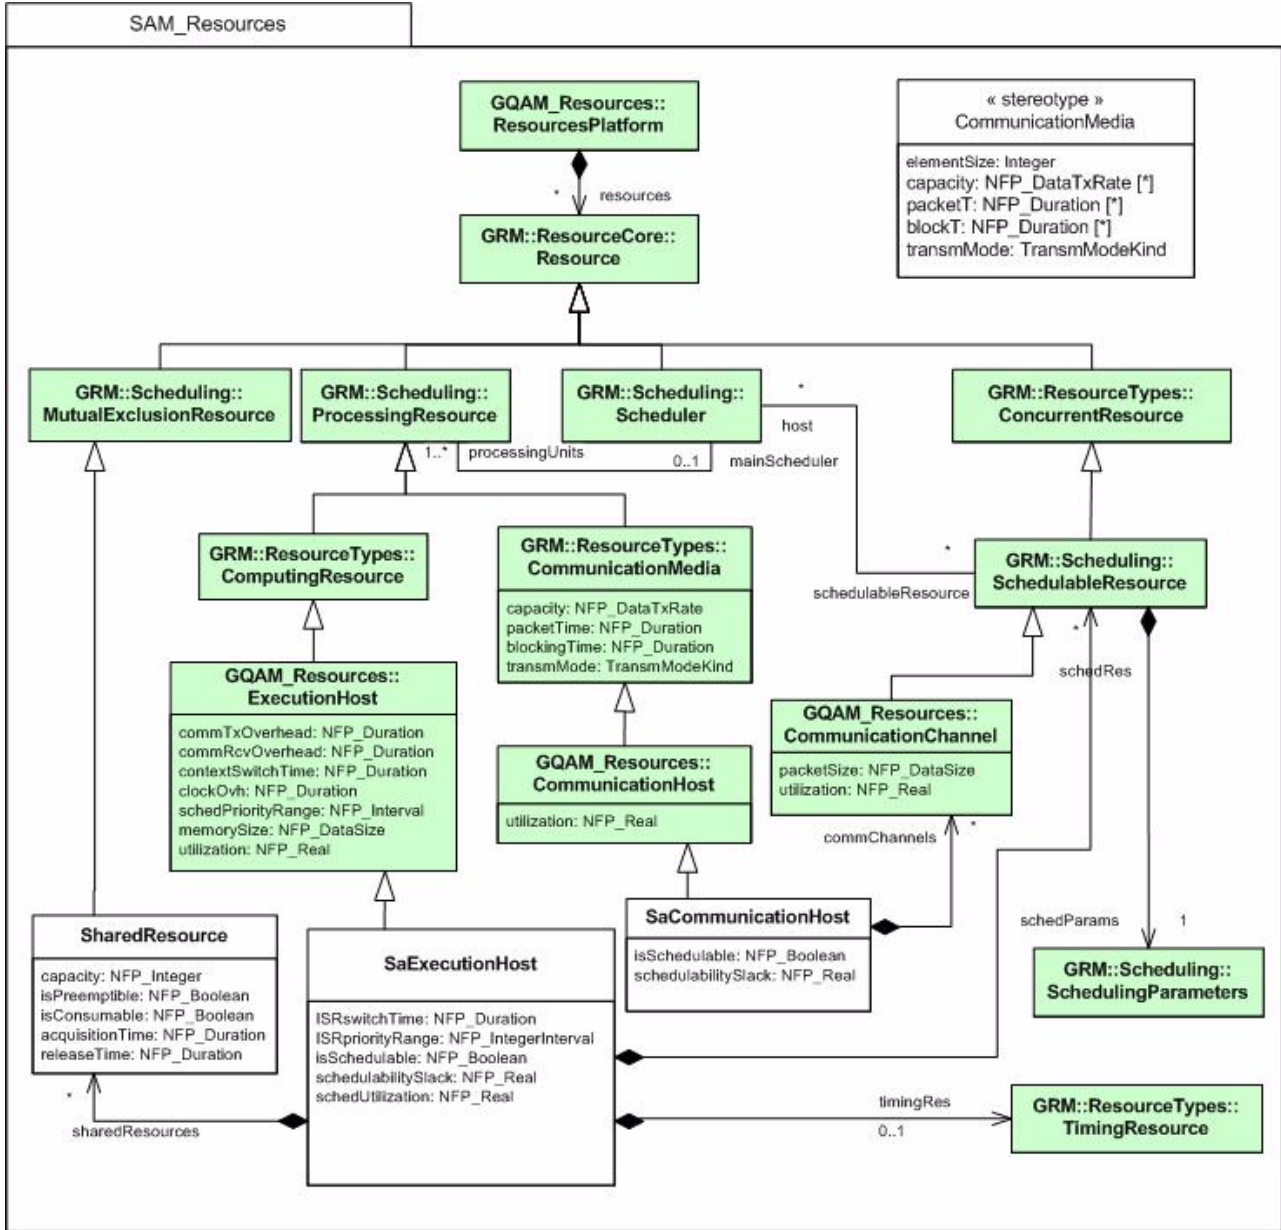

Figure 16.6 - The SAM Resources domain model

Execution Hosts own shared resources as for example I/O devices, DMA channels, critical sections or network adapters. Shared resources are dynamically allocated to schedulable resources by means of an access policy. Common access policies are FIFO, priority ceiling protocol, highest locker, priority queue, and priority inheritance protocol.

16.2.4.1 Types of Model Analysis Methods

Two major categories of scheduling policies, and therefore two types of analysis, are available. One category is static in nature - i.e., parametric decisions about scheduling importance are all made "up-front" and the entire collection of execution possibilities and contexts is known beforehand. The other category involves dynamic scheduling -i.e., scheduling decisions are made at runtime using information available within the dynamic context of execution. It is the intention of this specification to support both categories.

Depending on the policy, parameters like scheduling priority may be statically determined by the analyst, with or without the aid of model analysis tools, or dynamically by portions of the system that continuously analyze context and adjust internal parameters like priority. Earliest Deadline First scheduling is an example of such a dynamic activity. Deadlines - the amount of time remaining in which the defined work of a thread must be done - changes continually when that thread is not running. This means that the earliest deadline is a dynamically changing value. Rate Monotonic Analysis, on the other hand, is determined from the complete static set of schedulable threads, their resources, and rates of invocation.

Static scheduling and related model analysis

Rate Monotonic Analysis

Rate Monotonic Analysis assigns scheduling priority to periodic schedulable resources by ordering scheduling priority according to the frequency of repetition of execution - i.e., the rate by which a periodic schedulable resource needs to be scheduled to execute. The name Rate Monotonic means that the priority ordering is a monotonic function of the rate of execution. This model analysis technique can be extended to include both periodic and sporadic scheduling end-to-end flows. Detailed discussion of these topics can be found readily in the literature.

Deadline Monotonic Analysis

Rate Monotonic Analysis is used for analysis of periodic schedulable resources where the deadline coincides with the next required execution to start - i.e., the period and the deadline are the same. Sometimes this is not the case. A slight variation of RMA is deadline monotonic analysis where the deadline for a periodic schedulable resource needs not be the same as its period. Detailed discussion of deadline monotonic analysis can be found readily in the literature.

Dynamic Scheduling - value or utility based scheduling

Dynamic Scheduling deals with the condition where the values used to order the scheduling of the CPU are a changing function over time. Therefore, dynamic scheduling uses a scheduler that makes decisions based on importance of each schedulable resource, but the importance is continuously re-examined within the dynamic context of execution of the system containing the scheduler. This class of scheduling policy is often called value based or utility based scheduling; it uses a supplied function (which may be but doesn't have to be a function of time, $v(t)$) to obtain a value for scheduling importance.

Earliest deadline first is a simple concrete example of a specific value function; it is a widely used scheduling policy implemented in a dynamic scheduling manner in many domains, including the telecommunications community. Although earliest deadline is a popular value function the notion can be generalized to any value function that makes sense for a specific domain.

Value based scheduling is currently receiving significant attention.

16.3 UML Representation

We now examine how the domain concepts previously presented can be represented (mapped) in the UML modeling space. To provide the flexibility required by the RFP for this specification, the same stereotypes may be applied to a number of different kinds of modeling elements.

This sub-profile allows modelers to choose the style and modeling constructs, or to impose constraints, that they feel are best ones fittings to their needs. From a predictive point of view, most of schedulability analysis models are intrinsically instance-based. Nevertheless, high-level descriptor/type-based models and state-based models can also be annotated with non-

functional characteristics, and then concrete analysis models may be instantiated for specific analysis runs. For instance, stereotypes for schedulability analysis modeling apply to both instance concepts as well as generic descriptor concepts. Either form may be used since there are no semantic differences as far as the interpretation of the results is concerned. The choice depends on circumstances (i.e., whichever model is more readily available) or individual preference of the modeler. The tagged values of descriptor elements should be viewed as defaults for derived instances, which can override the defaults.

16.3.1 Profile Diagrams

In this Section we show the UML extensions for the SAM sub-profile. The SAM package (stereotyped as profile) defines how the elements of the domain model extend metaclasses of the UML metamodel.

An analysis context (real-time situation) for schedulability analysis is modeled as a stereotype "SaAnalysisContext" (Figure 16.7). It specializes the GQAM GaAnalysisContext stereotype, and the latter in turn specializes the VSL "ExpressionContext" stereotype, which extends UML NamedElement. Although this could seem too general, common extended elements are UML Classifier, for more complex models, and whatever UML Behavior kind, for the simplest cases. This means that these model elements are used as collectors of schedulability analysis sub-views, i.e., workload behavior models and platform resources model. Note that in the simplest cases, an analysis context can be extracted from a behavior model that has explicit allocations (stereotypes from the Allocation profile) to resources elements.

"GaWorkloadBehavior" and "GaResourcesPlatform" are used directly from GQAM, where they extend UML NamedElement and Classifier respectively.

An end-to-end flow maps to UML NamedElement. Although this could seem too general, common extended elements are UML Behaviors such as Interaction or Activity. The reason by which it extends UML NamedElement is that it might extend other elements like for instance UML ActivityPartition. A "SaEndToEndFlow" will make reference implicitly to one or more GQAM "GaWorkloadEvent" and to one "GaScenario" commonly by means of a containment relationship (owned elements) or allocation stereotypes.

Figure 16.7 - The SAM Profile: Analysis Context and Workload Behavior elements

A "GaWorkloadEvent" extends UML NamedElement in GQAM. Nevertheless, more common extended elements are: UML AcceptEventAction, Event, Trigger, InitialNode, or Message. The relationship between "GaWorkloadEvent" and "GaScenario" is either via collocation of the stereotypes, or by a UML meta-association between the two elements stereotyped (e.g., Event-Trigger-Behavior, InitialNode-ControlFlow-Action, Message-ExecutionSpecification-Behavior).

The GQAM "GaScenario", and the SAM "SaStep" and "SaCommStep" extends "TimedProcessing" of the MARTE Time profile. The latter extends UML Actions, Behaviors, ExecutionSpecification, and Messages. The Allocation stereotypes can be used to associate steps with particular resources. "GaStep" can call "RequestedServices", which is a kind of "GaStep" (see the GQAM chapter). This is used to make calls from a instance-based behavioral element (e.g., UML ExecutionSpecification) to descriptor-based behavior elements (e.g., UML BehavioralFeature).

"GaTimedObserver" specializes "NfpConstraint", and the latter extends UML Constraints (see the NFPs profile). In general, "GaTimedObserver" are used to constrain other behavioral elements. For instance, "SaEndToEndFlow" has an association (timing) that define a meta-association between this element and UML constraints stereotyped as "GaTimingObserver", or its child stereotypes.

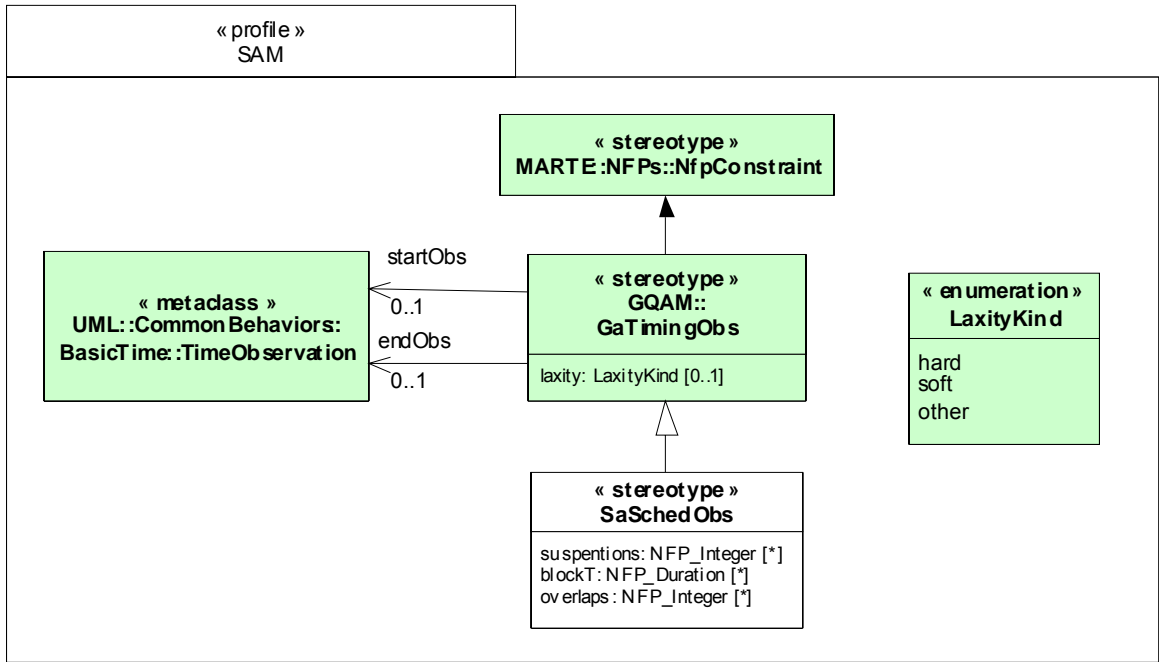

Figure 16.8 - The SAM Profile: Timing Observers

Resources stereotypes extend UML structural elements (Figure 16.9). These are indicated by stereotyping Classifier or InstanceSpecification (e.g., Classes, Nodes, Components) with the appropriate stereotypes ("SaCommHost", "SaExecHost", "SaSharedResource", "Scheduler", "SchedulableResource", "GaCommChannel"). The relationship between "SaExecHost" and the "SaSharedResource", "Scheduler", and "SchedulableResource" resources is established using the "Allocate" and "Allocated" stereotypes of the Allocation profile.

Figure 16.9 - The SAM Profile: Resources

16.3.2 Profile elements description

In this section, we describe the SAM stereotypes. These stereotypes are listed in alphabetical order. The detailed semantic descriptions corresponding to these stereotypes and tagged values are provided in Annex F.11 on page 545.

16.3.2.1 SaEndToEndFlow

The SaEndToEndFlow stereotype maps the EndToEndFlow domain element (section F.11.1, p. 545) denoted in Annex F. End-to-end flows describe a unit of processing work in the analyzed system, which contend for use of the processing resources. This is a conceptual entity only, which is represented by its concrete elements: end-to-end stimuli and end-to-end response.

Extensions

- UML::Classes::Kernel::NamedElement

Generalizations

- None

Associations

- None

Attributes

- isSched: NFP_Boolean [0..1]
indicates whether the flow meets all its deadlines.

- schSlack: NFP_Real [0..1]
provides a percentage measure by which the (effective) execution time of all the atomic processing units participating in the end-to-end response may be increased while still keeping the end-to-end flow schedulable.
- EndToEndT: NFP_Duration [0..1]
represents the predicted worst completion time latency of the end-to-end response measured from the arrival of the requested event. This applies if only one input end-to-end stimuli exist.
- EndToEndD: NFP_Duration [0..1]
represents the required worst completion time latency of the end-to-end response measured from the arrival of the requested event. This applies if only one input end-to-end stimuli exist.
- timing: TimedObs [*]
set of timing requirements or predictions that constrain local fragments or the global end-to-end execution flow.

Constraints

- None.

16.3.2.2 SaAnalysisContext

The SaAnalysisContext stereotype maps the SaAnalysisContext domain element (section F.11.2, p. 546) denoted in Annex F.

An analysis context is the root concept to collect relevant quantitative information for performing a specific analysis scenario. Starting with the analysis context and its elements, a tool can follow the links of the model to extract the information that it needs to perform the model analysis. Analysis contexts are also known as real-time situations in the schedulability analysis domain.

Extensions

- None

Generalizations

- GaAnalysisContext (from GQAM)

Associations

- None

Attributes

- isSched: NFP_Boolean [0..1]
It indicates whether all the timing constraints defined for the analysis context are respected.
- optCriterion: optimalityCriterionKind [0..1]
The optimalityCriterion attribute denotes a global criterion used to determine a schedule for the context analyzed (e.g., meet all hard deadlines, minimize the number of missed deadlines, minimize the mean tardiness, maximize flow).

Constraints

- None.

16.3.2.3 SaStep

The SaStep stereotype maps the SaStep domain element (section F.11.3, p. 547) denoted in Annex F.

A SaStep is a kind of GaStep that begin and end when decisions about the allocation of system resources are made, as for example when changing its priority.

Extensions

- None

Generalizations

- GaStep (from GQAM)

Associations

- sharedRes: SaSharedResource [*] {subsets GQAM_Workload::GaStep::usedResources}
set of shared resources that will be locked during the execution of this step.

Attributes

- deadline: NFP_Duration [0..1]
defines the maximal time bound on the completion of this particular execution segment that must be met.
- spareCap: NFP_Duration [0..1]
amount of execution time that can be added to the step without affecting schedulability.
- schSlack: NFP_Real [0..1]
percentage by which the execution time of the step can be increased (positive values) or should be decreased (negative values) in order to reach the schedulability limit.
- preemptT: NFP_Duration [0..1]
length of time that the step is preempted, when runnable, to make way for a higher priority step.
- readyT: NFP_Duration [0..1]
effective release time expressed as the length of time since the beginning of a period; in effect a delay between the time an entity is eligible for execution and the actual beginning of execution.
- nonpreemptionBlocking: NFP_Duration [0..1]
maximum length of time within the context of the current SaStep that a ready SaStep is blocked while lower priority schedulable entities are nonpreemptible.
- o selfSuspensionBlocking: NFP_Duration [0..1]
maximum length of time within the context of the current SaStep that a ready SaStep voluntarily yields the Processing Resource.
- numberSelfSuspensions: NFP_Integer [0..1]
maximum number of times an SaStep self suspends during its execution. (MUST be provided if selfSuspensionBlocking is provided.).

Constraints

- None

16.3.2.4 SaCommStep

The SaCommStep stereotype maps the SaCommunicationStep domain element (section F.11.4, p. 548) denoted in Annex F.

A SaCommStep is a kind of step that represents a usage of a communication media.

Extensions

- None

Generalizations

- CommStep (from GQAM)

Associations

- None

Attributes

- deadline: NFP_Duration [0..1]
defines the maximal time bound on the completion of this particular transmission that must be met.
- spareCap: NFP_Duration [0..1]
amount of execution time that can be added to the step without affecting schedulability.
- schSlack: NFP_Real [0..1]
percentage by which the execution time of the step can be increased (positive values) or should be decreased (negative values) in order to reach the schedulability limit.

Constraints

- None

16.3.2.5 SaExecHost

The SaExecHost stereotype maps the SaExecutionHost domain element (section F.11.5, p. 548) denoted in Annex F.

A CPU or other device which executes functional steps. The SaExecHost stereotype adds schedulability metrics, interrupt overheads and utilization of scheduling processing.

Extensions

- None

Generalizations

- GaExecHost (from GQAM)

Associations

- None

Attributes

- ISRsSwitchT: NFP_Duration [0..1]
context switch time of ISR (Interrupt Service Routines) interruptions.
- ISRprioRange: NFP_IntegerInterval [0..1]
range of ISR priorities supported by the platform.
- isSched: NFP_Boolean [0..1]
indicates whether all the timing constraints defined for the execution host are respected.
- schSlack: NFP_Real [0..1]
percentage by which the execution time of all the steps running in this execution host can be increased (positive values) or should be decreased (negative values) in order to reach the schedulability limit.
- schedUtiliz: NFP_Real [0..1]
total utilization of scheduling services.

Constraints

- None

16.3.2.6 SaCommHost

The SaCommHost stereotype maps the SaCommunicationHost domain element (section F.11.6, p. 549) denoted in Annex F.

In a communication host (e.g., networks, buses), the related schedulable resource element is CommunicationChannel, which may be characterized by concrete scheduling parameters (like the packet size).

Extensions

- None

Generalizations

- GaCommHost (from GQAM)

Associations

- None

Attributes

- isSched: NFP_Boolean [0..1]
indicates whether the transmitted messages meet all its deadlines.
- schSlack: NFP_Real [0..1]
provides a percentage measure by which the (effective) transmission time of all the communication steps participating in the host may be increased while still keeping the system schedulable.

Constraints

- None

16.3.2.7 SaSchedObs

The SaSchedObs stereotype maps the SchedulingObserver domain element (section F.11.7, p. 549) denoted in Annex F.

SaSchedObs provides prediction about scheduling metrics such as overlaps, the maximum number of suspensions caused by shared resources or the blocking time caused by the used shared resources. All these metrics are relative to the interval defined by the reference and observed events.

Extensions

- None

Generalizations

- TimedObs (from GQAM)

Associations

- None

Attributes

- suspensions: NFP_Duration [*]
the maximum number of suspensions caused by shared resources.
- blockT: NFP_Duration [*]
the blocking time caused by the used shared resources.
- overlaps: NFP_Duration [*]
in case of soft timing constraints, this indicates how many instances may overlap their execution because of missed deadlines.

Constraints

- None

16.3.2.8 SaSharedResource

The SaSharedResource stereotype maps the SharedResource domain element (section F.11.8, p. 550) denoted in Annex F.

Execution Hosts own shared resources as for example I/O devices, DMA channels, critical sections or network adapters. Shared resources are dynamically allocated to schedulable resources by means of an access policy. Common access policies are FIFO, priority ceiling protocol, highest locker, priority queue, and priority inheritance protocol.

Extensions

- None

Generalizations

- MutualExclusionResource (from GRM)

Associations

- None

Attributes

- capacity: NFP_Integer [0..1]
number of permissible concurrent users, for example using a counting semaphore.
- isPreemp: NFP_Boolean [0..1]
if the resource can be preempted while it is being used.
- isConsum: NFP_Boolean [0..1]
indicates that the resource is consumed by use.
- acquisiT: NFP_Duration [0..1]
time delay suffered by an action between being granting access to a resource and the availability of the resource.
- releaseT: NFP_Duration [0..1]
time delay suffered by an action between initiating release of a resource and the action becoming eligible for execution again.

Constraints

- None

16.3.3 Examples

We now examine how the domain concepts and the profile previously presented can be used for modeling schedulability-aware systems.

The annotations have been made over a case study application for the real-time modeling and analysis of a simple distributed system for the teleoperated control of a robotized cell.

The application system (see Figure 16.10) is composed of two processors interconnected through a CAN bus. The first processor is a teleoperation station (Station); it hosts a GUI application, where the operator commands the robot and where information about the system status is displayed. The second processor (Controller) is an embedded microprocessor that implements the controller of the robot servos and its associated instrumentation.

The software architecture is described by means of the class diagram shown in Figure 16.10. The software of the Controller processor contains three active classes (called rtUnits in MARTE, see chapter 13) and a passive one which is used by the active classes to communicate. Servo Controller is a periodic rtUnit that is triggered by a ticker timer with a period of 5 ms. The Reporter rtUnit periodically acquires, and then notifies about, the status of the sensors. Its period is 100 ms. The Command Manager rtUnit is aperiodic and is activated by the arrival of a command message from the CAN bus.

The software of processor Station has the typical architecture of a GUI application. The Command Interpreter rtUnit handles the events that are generated by the operator using the GUI control elements. The Display Refresher rtUnit updates the GUI data by interpreting the status messages that it receives through the CAN bus. Display_Data is a protected object (called ppUnit in MARTE, see chapter 13) that provides the embodied data to the rtUnit in a safe way. Both processors have a specific communication software library and a background task for managing the communication protocol.

Figure 16.10 - Example of the Teleroperated Robot application: Structural View

To organize the UML models annotated for schedulability analysis, we adopt the concept of views, which represent the concern models composing the SAM's real-time situation concept. In this way, we provide separated diagrams for specifying the SAM concepts of workload behavior, and resources platform. Next, we show some examples that illustrate this organization.

16.3.3.1 Example of Workload Behavior model

The workload behavior situation to be analyzed contains three end-to-end flows with hard real-time requirements. They all use the processing resources Station, Controller and CAN_Bus and interact by accessing protected objects.

The control servos end-to-end flow executes the Control response with a period and a deadline of 5 ms. The report process end-to-end flow transfers the sensors and servos status data across the CAN bus, to refresh the display with a period and deadline of 100 ms. Finally, the Execute Command end-to-end flow has a sporadic workload event pattern, but its inter-arrival time between events is bounded to 1 s.

Figure 16.11 illustrates an UML Activity diagram that represents a workload behavior model consisting of the three above-mentioned end-to-end flows characterized by their workload events and behavior scenarios. These three end-to-end flows explicitly introduce the semantic of concurrency for the modeled activity partitions. Workload events annotating UML AcceptEventActions introduce the semantic of event sequence arrivals for the execution of each callBehaviorAction (Control, Report and Command). We also annotate non-functional properties for the three kinds of extensions. An end-to-end flow is characterized by an end-to-end deadline and the request event stream by their the arrival patterns. Behavior

scenarios are annotated with expressions of variables (\$r1, \$u1, \$e1, \$wcet1, \$pR, etc.). In general, when attributes are annotated with variables, the model indicates to the analysis tools that these attributes must be computed and returned to the UML model.

Figure 16.11 - Example of end-to-end flows situations model

In Figure 16.12, we present one of the three scenarios that models the Report behavior scenario. Note that a "GaScenario" stereotype (which is annotating UML CallBehaviorActions) can also annotate the behavior itself. Behaviors can be Interactions, State Machines and Activities. The behavior model elements allow for representing end-to-end behaviors and the precedence between the processing steps involved in the scenario. In our example, we applied it to sequence diagrams (see Figure 16.12). Observe that the stereotypes "SaStep" and "SaCommStep" extend UML messages. In general, steps annotating UML messages represent the execution load of the associated UML ExecutionSpecification at the reception of the message. In this example, "SaSharedResource" elements are UML Lifelines of the sequence diagram. The chain of steps (connected by the successor-predecessor patterns) conform the model of the "GaScenario". "SaStep" elements include worst and best case execution times, and "SaCommStep", in turn, the size of the message transmitted or received.

Figure 16.12 - Example of Behavior Scenario model

16.3.3.2 Example of Resources Platform model

In Figure 16.13, we represent the domain concept of resource platform since an analysis viewpoint. In this case, we use a structured classifier to collect a set of resource instances. The structured classifier represents the resources platform under analysis. The processing resources defined in Figure 16.10 (Station, CAN_Bus, Controller, RobotArm) are represented as parts of the resources platform. These parts are annotated with non-functional characteristics required for schedulability analysis. In addition, a scheduler instance (a part again) represents the OS scheduler based on fixed priority scheduling.

Additionally, a set of schedulable resources instances are modeled as parts that are allocated on processing resources. Schedulable resources are annotated with a priority parameter.

Note that execution and communication steps are allocated to this set of schedulable resources by means of the stereotype allocated applied to lifelines in Figure 16.12. This means that the execution specifications realized in the lifelines are processed in the context of the target schedulable resources.

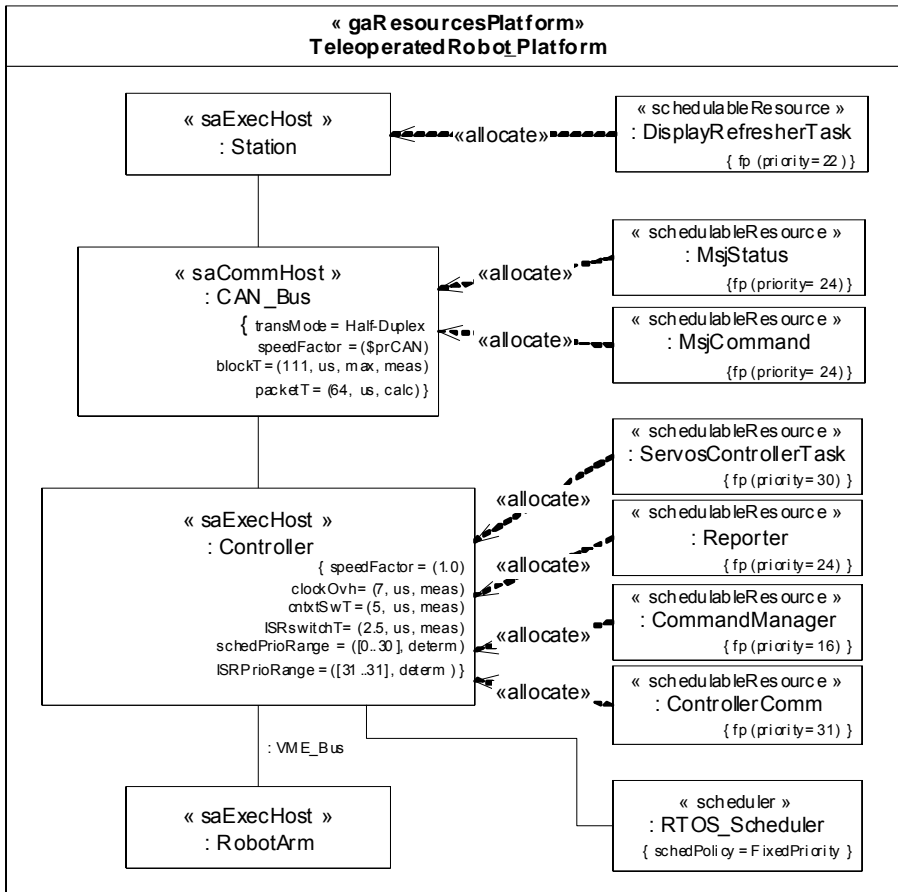

Figure 16.13 - Example of Resources Platform model

16.3.3.3 Example of Analysis Context model

In order to define the analysis context for a given pair of workload behaviour and resources platform models, we illustrate how to use structured classifiers (Figure 16.14 on page 312). In this example we collect analysis views by means of parts instantiating workload behavior (normalMode Activity in the example) and resources platform (TeleoperatedRobot_Platform StructuredClassifier in the example) models. In addition, this example illustrates how to parameterize analysis results by means of variables (see Annex VSL for the profile of variable definition). Note that "GaAnalysisContext" inherits from "ExpressionContext", which enable "SaAnalysisContext" elements to be used as contexts or namespaces of variables. Variables extend UML Property.

N.B.: Note that this mechanism does not replace the basic annotation mechanism of variables declared in tags by which a model indicates the information to return by analysis tools. Our aim is to provide a more flexible and alternative way to communicate analysis intents to analysis tools by means of UML Property elements (stereotyped as variable: "var").

Particularly, the context under consideration defines four variables especially chosen to analyze certain parameters of interest. isSched_System defines the global scheduling correctness regarding all the required deadlines annotated in the context under analysis. The variables wcet_Report, procRate_CAN (CAN's processing rate), and period_Report actuates are parameters to study. In order to define the semantics of these variables in the context of the modeled system, we specify CallVariableExpression (see the Annex VSL) in their default values. These call variable expressions make

reference to variables declared in the context of the models under consideration. Thus, isSchSys is a variable defined for the isSched tag of the "SaAnalysisContext" stereotype. The variables wcet1 and pR are variables defined in the workload behavior model named NormalMode (Figure 16.11) and prCAN is a variable declared in the TeleoperatedRobot_Platform model (Figure 16.13).

In order to analyze different situations we instantiate the analysis context and define the actual values for the proposed variables. For instance, the UML InstanceSpecification named Schedulability defines isSched_System as the information to return ("\$v0" expression) as a calculated value (source slot of the NFP defined as "calc"), and the other variables are inputs to the analysis tool (source slot of the NFPs defined as "determ"). The result value returned by analysis tools is shown in red. In this case, the system has been determined to be schedulable.

More complex scenario analysis can be constructed for sensitivity analysis. For example, the UML InstanceSpecification named SensitivityAnalysis, defines isSched_System as a required value "true" (source slot defined as "req"). It actuates as a pivot parameter for calculating the other three variables, which in turn, are defined as results of the analysis (calc). Thus, the "maximum" worst case execution times of the Report response, while keeping the system schedulable is calculated, is 50 milliseconds. The "minimum" processing rate or speed factor (current measurements for the CAN message transmission speed are defined for a value of 1) is 0.2, while still keeping the system schedulable. Finally, the period of triggering of the Report end-to-end flow can be reduced to 10 milliseconds by still meeting all the deadlines.

Figure 16.14 - Example of parametric Analysis Context situations

Notice that most analysis tools operate on a simplified view of a system, as illustrated in this example. However, this profile allows annotations and interpretations to be attached at the level of detail desired by the designer. Indeed, even if the specification contains extreme detail, the annotations may optionally be applied to aggregates. This is an overriding reason to find a path to annotations that require a minimum of effort, with a minimum of additions to the design model, and with clear, non-fragmented specifications of NFPs. It is also essential that NFPs can be attached to a real software design, rather than requiring a special version of a design created only for analysis.

17 Performance Analysis Modeling (PAM)

17.1 Overview

In MARTE, "performance modeling" describes the analysis of temporal properties of best-effort systems and soft-real-time embedded systems, including systems supplying information, web-based services, enterprise services, multimedia, telecommunications, and networked services. Performance measures (analysis outputs) are statistical, such as mean throughput and delay, or the probability of missing a target response time. Input parameters to the analysis may also be probabilistic, such as a random arrival process, random execution time for a media frame, or a probability of a cache hit. The common performance analysis techniques include simulations, extended queueing models, and discrete-state models such as Stochastic Petri Nets. Behaviour is often regarded as non-terminating for the purposes of analysis (steady state behaviour, for example for capacity analysis).

Performance analysis includes single-case analysis for a given set of input parameters, or multcase analysis such as:

- sensitivity analysis which explores a parameter space, to find ideal operational parameters or to identify risky workload situations. Sensitivity analysis may also include alternative scenarios, platforms, physical deployments, and configurations.
- Scalability or capacity analysis which explore the capabilities of the design or configuration.

There is explicit support for multcase analysis in the parameters of the AnalysisContext.

The performance domain employs and extends the Generic Quantitative Analysis Modeling (GQAM) domain of Chapter 15. It employs features such as the WorkloadEvent description of the stream of arriving events, focussing on some of the workload types (open and closed arrivals, workload generators and traces), and the behavior-causality model of Scenarios and Steps. It extends the properties of Steps to include more kinds of operation demands during a step, and the possibility of an asynchronous (non-synchronizing) parallel operation. Other extensions a Step subtype PassResource which identifies the passing of a resource (usually a SharedResource) from one process to another.

The increment to the GQAM domain model is shown in Figure 17-1 and Figure 17.2, broken into two packages, PAM_Workload and PAM_Resources. Some elements are shown in both diagrams where there are associations between resources and behavior elements. For elements from other domains, only the attributes of interest for performance analysis are shown.

17.2 Domain view

17.2.1 The PAM_Workload package

Performance analysis is determined by how the system behaviour uses system resources. Important resources include hardware ExecutionEngines, concurrent process threads (ScheduledResources), and LogicalResources defined by the software. A logical resource can be any entity to which the software requires access, and for which the program may have to wait at some point. Thus a semaphore is in this sense a resource, as is a lock, or a buffer, or a block of memory. A pool of access control tokens can be modeled as a logical resource.

A process resource, or pool of process threads, is also a kind of logical resource which is modeled separately, by the concept of SchedulableResource imported from the General Resource domain model (GRM). Because processes may be identified in behaviour specifications by other entities (lifelines and swimlanes in particular), a special concept of RunTimeObjectInstance is introduced to represent an alias for a process resource.

Figure 17.1 - Part of the performance domain model relevant to behavior

Resources which are not modeled within the software design may also have an impact on performance. This domain model identifies "external operations" by such resources by a name (a string), so they can be modeled in the performance environment. An example is the use of a TCP connection, which is not modeled in the software specification, but for which customized simulators exist. The same considerations might apply to database or storage subsystems.

Demands by a Step for external operations are described by the pair of properties externalOpDemand and externalOpCount. The first is an ordered list of operation names (strings), and the second is an ordered list (in the same order) of the number of demands made during one execution of the Step. The number may be an exact number (an integer), an average value (real) or a probability distribution defined in the NFP.

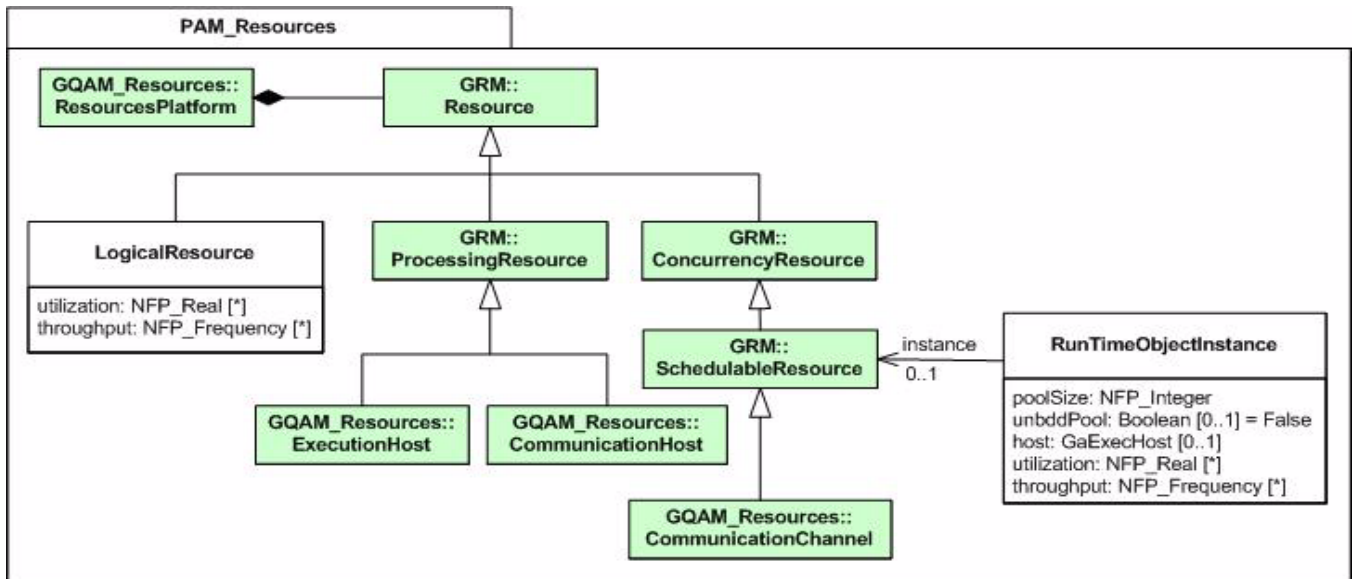

Figure 17.2 - Part of the performance domain model relevant to resources

Performance properties of different system elements fall into a small number of different measures, as discussed in Chapter 15. For instance the term throughput (in operations/sec) is applied to the system as a whole, for handling of requests, but also to a single process, or component, or processing step. Because of this uniformity, one set of property names is defined in Table 15-1 to be applied at will to different behaviour and resource entities. These NFPs are used here also. Typical performance properties include average response time, mean throughput capacity, resource utilization, and the probability of missing a delay target. However more sophisticated properties can be investigated, and in general performance analysis uses input and output properties which may be any statistical measure of five types of quantities:

- Duration (e.g.respT) (e.g. as an operation delay, or as a response time), NFP_Duration.
 - also forced duration (e.g. blockT) (a duration which is part of the operation, such as a user think time), NFP_Duration
- Frequency (or throughput. e.g. of events or operations) NFP_Frequency.
- Probability (e.g. of occurrence of some event), NFP_Real.
- Repetitions, for a loop repetition or a repeated operation, NFP_Real. This is represented as Real rather than integer so that mean values can be represented.
- Message size or memory size, NFP_DataSize.

The analysis associates a BehaviorScenario with the concepts of workload, request, service and response. The workload defines the frequency or intensity of occurrence of requests for the service; the details of the service given to each request are defined by the BehaviorScenario (giving the resources and operations including their demand parameters), and the response is the result, including its properties of delay, frequency, and probabilities. Resources are associated with one or more BehaviorScenarios, constrain their properties, and have their own properties which include holding time and utilization (which is the probability that the resource is busy, or a mean count of the number of busy resource units).

17.2.2 Outline of domain concepts

17.2.2.1 Performance AnalysisContext and Workload

The AnalysisContext (from GQAM) corresponds to the scope of a study or evaluation. It combines the system represented by its behaviour (BehaviorScenarios) and its resources (from GQAM), with one or more workloads. It has a set of parameters which are used in expressions which define system input parameters, and which define the range of variation of cases which may arise within the study.

A performance context specifies one or more BehaviorScenarios that are used to explore various dynamic situations involving a specific set of resources. For instance, a performance context may describe a "busy hour", during which the maximum processor load is expected and therefore imposing the greatest likelihood of performance problems, such as missed deadlines. For a given system specification, there may be many performance contexts with overlapping resources, but one BehaviorScenario is specific to one performance context.

One UML specification may give rise to several performance models, due to variations in system usage, workload, allocation/deployment, and configuration. We will call these different models cases; they are supported by parameterizing the specification. Parameterized NFPs are supported by the use of:

- Variables global to the AnalysisContext, defining the variations.
- Variable names in place of numeric values of input properties for model elements.
- Functional dependencies of the input properties on the global variables, to define values.

Variables can then be used to specify:

- Workload intensity, through arrival rates or concurrency (population size).
- System scaling through multiprocessors or replication.
- Data record size (and then various demands, through functions).

Analysis cases are defined outside the UML specification by defining groups of values of variables, with one group of values for each case. These may be expressed in a table with a column for each case and a row for each variable.

Additional sources of variation may arise with different configurations and environments. Some of these variations are independent of the UML model, for example the choice of middleware or operating system. The construction of performance models can incorporate directives to compose the application with a stated environment, using a library of submodels for environments (described above). These also become case parameters.

Figure 17.3 - Analysis over cases

17.2.2.2 Behavior

The unit of description of behaviour is the BehaviorScenario, which corresponds to a behaviour diagram (interaction, activity or state-machine diagram). It is a sequence of actions (called Step here for its performance aspects), with predecessor-successor relationships which may include forks, joins and loops. Steps indicate the demands of the system on its resources, both for execution on the host processor of the step (called its hostDemand attribute) and for other resources.

Other resources can be acquired (and released) explicitly using subtypes of Step called ResourceAcquire and ResourceRelease, in which the resource is identified directly. Still further resources can be utilized through demands by a Step for Services (like calls) which may involve arbitrary resource combinations. One kind of Service, by an ExternalResource, shows the use of resources outside the UML model.

The input attributes of a Step include its probability (following a branch, or in an opt or alt CombinedFraqment), a repetition count (for a repeated step, such as a loop CombinedFraqment), and a "noSync" attribute (following a fork, or on an asynchronous message or par operand) to explicitly indicate that a parallel branch does not join. Behaviour using noSync may provide increased concurrency and increased performance.

A Step may be refined by another BehaviorScenario. In an Interaction Diagram the sub-BehaviorScenario may be the operand of a CombinedInteraction; in an Activity Diagram it may be the contents of a StructuredActivity. A BehaviorScenario that responds directly to requests by a Workload may be termed a "top-level" BehaviorScenario, while others are sub-scenarios.

In a performance model the system behaviour is often non-terminating, that is it cycles forever, repeating the top-level scenarios as defined by the workload intensity.

Resource demands by a step include its host execution (CPU) demand, acquisition of a logical resource, and demands for services which are not defined in the same behaviour definition, but are provided by some system component, or by the platform or the environment, or by an external system.

17.2.2.3 Workload

A context may have any number of workloads, representing different sources of requests or initiations of operations. Each workload has a distinct mechanism for initiating requests, its own load intensity, and its own QoS requirements. In a performance analysis, a workload corresponds to a class of traffic, with a mechanism which may be either open or closed.

Behaviour is initiated by a request event. An open workload is a RequestEventStream in which the events arrive at a given rate in some predetermined pattern (such as clocked or Poisson arrivals), or by a trace.

A closed workload defines a stream generated by a fixed number of active or potential users or jobs which cycle between demanding to execute the BehaviorScenario, and spending an external delay period (some times called a Think Time) outside the system, between the end of one response and the next request. A system may have any combination of open and closed workloads. Further, a closed workload may combine requests for different BehaviorScenarios in some sequence; in general a mechanism to describe this is called a WorkloadGenerator, governed by a state machine making requests for operations. ClosedWorkload is a special case.

The same BehaviourScenario concept describes execution of a request for a service by an external resource, which was discussed above. The operation size parameter can be used in such requests to define the service time of the request, when executed. For example a file service request might define the file size; then a performance submodel for the file system could use this parameter to work out the demands on the various resources in the file system, for each request.

17.2.2.4 Service

It is normal in performance analysis to speak of services, with offered and demanded quality of service. An informal expanded view of behaviour with ServiceDemands and OfferedServices is shown in Figure 17-4 and used in the following discussion.

A Service is a pivotal concept in performance. Requests queue for service by some resource, and may have a required quality of service. The actual service is defined in general by a BehaviorScenario, with a provided quality of service. It may be incorporated into the modeled behavior in three ways:

- By making a serviceDemand from a Step to a RequestedService, representing an operation offered at some interface, which is in turn defined by a BehaviorScenario.
- By making a behaviorDemand from a Step to directly invoke a BehaviorScenario, which defines a logical service offered in some way by the system.
- By making an extOpDemand from a Step to request an external service, which is defined in the performance environment outside the UML model.

External services vary depending on how much is defined in the UML model. For instance if the network is defined in the deployment then a message transmission is defined within the UML model, but if no network is specified it is an external service.

In the performance model, behavior can be composed flexibly from units defined by scenarios, by service operations embedded in components, and by external operations, as shown in Figure 17.4. This provides a toolkit that suits many different software design structures, and situations in which different kinds of performance information is available.

For component or platform services defined in the UML document, a submodel can be made and composed with the model of the defined services, through service demands. As an abstraction, for systems in which there is no such submodel, the equivalent behavior can be described by a subscenario and composed through behavior demands. For some kinds of platform services the costs can be included as overhead parameters of the host devices.

Figure 17.4 - Informal view of Services and Behaviour

17.2.2.5 Resources

In performance modeling based on queues, resources may be modeled as servers. An active resource is self-contained (e.g. a CPU) and has a characteristic service time for each class of service it offers. A passive resource may be acquired and released during a BehaviorScenario, and has a holding time which is determined by the behaviour (e.g. by the sub-scenario) between acquisition and release, which defines the class of service. An external resource is an active resource which is an abstraction for an external sub-system of any kind.

Software components, like resources, offer services which are defined by sub-scenarios. The steps of the sub-scenario define the use of other components and resources during a service. A component has a set of interfaces, each of which offers one or more of the services of the component. In software terms a single service may be defined as the response to one interface method, or to any one of a set of interface methods (methods may be clustered as a form of abstraction in the performance analysis). A software component may also be a passive resource (a process or thread) if its execution is restricted in some way. If there is no limit in the number of simultaneous concurrent active executions of the component, it optionally may be regarded as a special kind of "infinite resource", or as not a resource; the two concepts are equivalent.

17.2.2.6 Communications Channels

A message between two objects is conveyed by some mechanism:

1. If the objects are in the same process, it is conveyed by the language runtime.
2. if the objects are in different processes in the same node (ProcessingHost) it is conveyed by the operating system,
3. if they are of different nodes it is conveyed by a system layer we will term a CommChannel. This may be a middleware layer (a web services connection, a CORBA connection, a Java Remote Method Invocation, an MPI (Message-Passing Interface) connection in a grid, a socket or secure socket connection), or a more complex infrastructure such as a publish-and-subscribe system.

To give the modeler flexibility, these will be modeled in five different ways, of increasing detail and complexity (levels of detail):

1. Within the same node, language runtime costs and operating system costs are ignored by default; they are part of the scenario. If the interprocess communication cost per byte of the ProcessingHost is defined, that is used instead to calculate a hostDemand.
2. Between nodes the default is to determine node hostDemands from the sending and receiving overhead on the nodes (attributes of the two ProcessingHosts) and insert the latency of the link (an attribute of the connecting CommunicationsHost).
3. Between nodes the conveyance of the message may also be modeled as an external operation, invoking a submodel of the communications layer. If this demand is defined it over-rides the default. It is an attractive option for modeling the behaviour of the internet and the complexities of the TCP protocol.
4. Between nodes a communications layer such as CORBA may be defined as a UML StructuredClass offering send and receive operations to the two end-point processes. This layer is denoted as a CommChannel with a conveyance operation demanded by the CommunicationsStep in the scenario. Its service is defined by a BehaviorScenario defined for the send operation and the combination of the two end-point processes. The scenario may involve directory look-ups, authorization and redirection of requests. If a serviceDemand for this operation is defined it over-rides the default.
5. Between nodes a complex communications protocol can be modeled by a pure BehaviorScenario not associated with

a system component, but describing a collaboration of the hosts. For example in a publish-and-subscribe system a message is transferred by posting it to a repository, which then informs subscribers of the message. They finally access it themselves, at which point the message is delivered. If a serviceDemand for this operation is defined it overrides the default.

Each message with performance significance is defined as a kind of Step called a CommunicationStep, in sequence in the BehaviorScenario. Its annotations determine which level is used to model the cost and delay of communications. Figure 17.5 shows these definitions as dependencies, for both cases.

Notice that if the channel is a CommunicationsEngine with a rate parameter, its transmission demand may define the latency.

(a) Detail Level 2, conveyance modeled at the hardware level

(b) Detail levels 4 and 5: using a communications layer

Figure 17.5 - Roles in modeling the transmission of a message

From the above discussion, the model for levels 4 and 5 defined by a BehaviorScenario for transmission, either associated with CommChannel or invoked explicitly. For level 3 there is an implicit three step scenario of (send overhead on sending host, latency delay, receive overhead on receiving host). The domain model to support communications modeling is shown in Figure 17.5.

Figure 17.6 - Domain model for communications in performance modeling

17.2.2.7 Types of Performance Analysis Methods

A sub-profile for performance analysis should support modeling tools for building different kinds of performance models. Most modeling tools deal with one or more of the following common types of models:

- Queueing models define customer classes (workloads) which execute particular aspects of the software, which are captured in different scenarios. In the simplest queueing models it is only necessary to define the class sizes or arrival rates, and the total average demands placed on each device in the system, during one execution of each scenario. In more complex queueing models the distribution of the demand may be required, there may be passive resources as well as devices, and the detailed scenario sequence may be required (for instance if it has parallel branches).

Queueing models calculate average throughput, utilization and response times for classes overall, and layered or extended queueing models also can calculate these figures for passive resources and for parts of BehaviorScenarios (scenario steps or resource-operations).

1. Simulation models define multiple logical tokens which execute the software, following the detailed BehaviorScenario structure and using execution time distributions for the operations of each step. There may be passive resources and they may have complex scheduling (for instance, LRU management of a cache).

Simulation models can calculate a wide range of measures including histograms and percentiles as well as average values.

2. Discrete-state models such as Petri Nets define tokens which execute the software, following the detailed BehaviorScenario structure. As in queueing models there may be open or closed classes of tokens for different

scenarios. Where tokens must be differentiated they are said to be colored. Petri Nets use places to define the progress of tokens and transitions to describe decisions, and the passage of time. Resources are described by additional places and tokens, and resource scheduling by transitions which execute scheduling decisions. Other forms of discrete-state models include Markov and Semi-Markov chains, Stochastic Process Algebras, and Stochastic Automata.

Performance Petri Nets and other discrete-state models typically calculate average measures but can provide more detailed measures such as higher moments and distributions.

17.3 UML representation

17.3.1 Profile diagrams

The profile is defined in the two diagrams that follow, and in text in the next section. Much of it re-uses extensions defined for Generic Quantitative Analysis Modeling (section 15.3.1, p. 250), prefixed Ga, and these extensions are shown again here to show that they are part of this sub-profile, though their definitions are given elsewhere. For the inherited stereotypes, properties (tags) which are important for performance analysis are shown here.

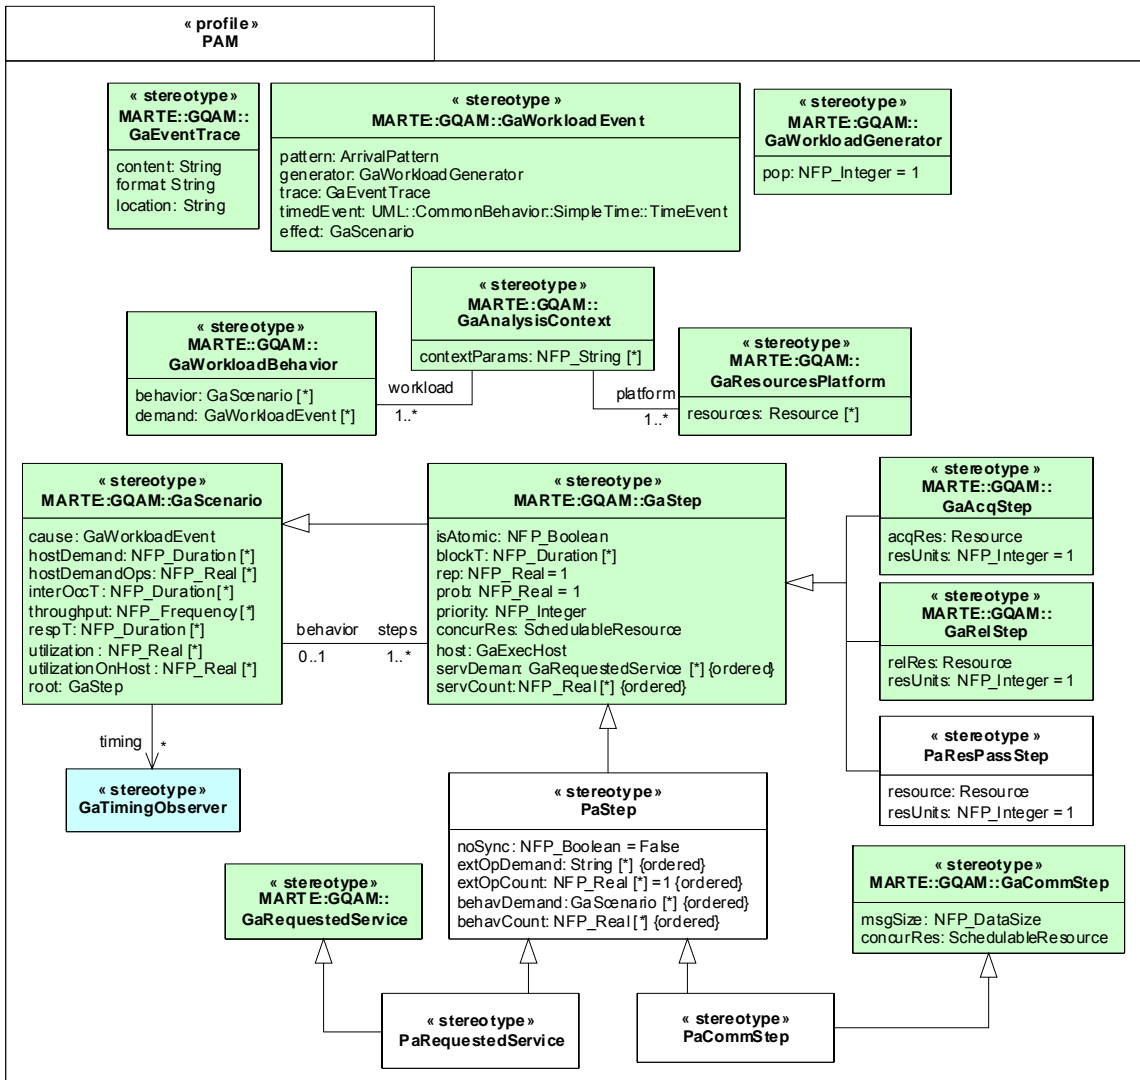

Figure 17.7 - Profile diagram of performance extensions for workload, behavior and time observations

Figure 17.8 - Profile diagram of performance extensions for resources

17.3.2 Profile elements description

Imported stereotypes from GRM and GQAM which are part of this subprofile are included in this list, however they are not defined. Where the semantics of the imported stereotype are affected by the performance domain, the semantics are outlined.

17.3.2.1 GaAnalysisContext (from MARTE::GQAM)

17.3.2.2 GaAcqStep (from MARTE::GQAM)

17.3.2.3 GaCommChannel (from MARTE::GQAM)

17.3.2.4 GaCommHost (from MARTE::GQAM)

17.3.2.5 PaCommStep

The semantics is similar to GQAM::GaCommStep, however the inheritance from PaStep incorporates the additional behavior definitions for operations during the step (external operations and behavDemand for a nested Scenario). The message conveyance may be executed by a combination of host middleware and network services.

Extensions

- None

Generalizations

- PaStep.
- GaCommStep (from MARTE::GQAM).

Associations

- None.

Attributes

- msgSize: NFP_dataSize [*]
the size of message to be transmitted by the step.
- concurResource: MARTE::GRM::SchedulableResource [0..1]
the logical communications channel by which the message is conveyed.

Constraints

- None

17.3.2.6 GaEventTrace (from MARTE::GQAM)

17.3.2.7 GaExecHost (from MARTE::GQAM)

In performance modeling, an GaExecHost can be any device which executes behavior, including storage and peripheral devices.

17.3.2.8 PaLogicalResource

The PaLogicalResource stereotype maps the LogicalResource domain element (section F.12.13, p. 556) denoted in Annex F.

A PaLogicalResource is a resource that can be acquired and released explicitly by AcqStep or RelStep. It may be a single-unit resource, as a mutex or exclusive lock, or have multiple units, as a buffer pool or an access token pool. A logical resource that is embodied as a software process is stereotyped SchedulableResource or PaRunTInstance instead

Extensions

- Classifier (from UML::Classes::Kernel).

Generalization

- Resource (from MARTE::GRM)

Associations

- None

Attributes

- poolSize: NFP_Integer [0..1] = 1
the number of units of the resource.
- utilization: NFP_Real [*]
the occupancy of the resource, expressed as the mean number of busy units of the resource. If poolsize = 1, there is one instance, and the utilization is the probability it is busy.
- throughput: NFP_Frequency [*]
the rate of requests to the resource.

Constraints

- None

17.3.2.9 GaRelStep (from MARTE::GQAM)

17.3.2.10 PaRequestedService

The PaRequestedService stereotype maps the RequestedService domain element (section F.12.9, p. 554) denoted in Annex F.

The semantics are similar to GQAM::GaRequestedService, however the inheritance from PaStep incorporates the additional behavior definitions for operations during the step (external operations and behavDemand for a nested Scenario).

Extensions

- Operation (from UML::Classes::Kernel)

Generalizations

- PaStep
- GaRequestedService (from MARTE::GQAM)

Associations

- None

Attributes

- None

Constraints

- None

17.3.2.11 GaResourcesPlatform (from MARTE::GQAM)

17.3.2.12 PaResPassStep

ResPassStep is applied immediately after a fork to indicate that a resource held before the fork is passed to this branch, and not shared by all the branches of the fork. Resource units that are held before the fork and not passed, are shared by all branches.

Extensions

- None

Generalizations

- GaStep (from MARTE::GQAM)

Associations

- None

Attributes

- resource: Resource [0..1] the identity of the resource of which some units are passed.
- resUnits: NFP_Integer [0..1] = 1 the number of units which are passed.

Constraints

- None

17.3.2.13 PaRunInstance

A stereotype for a swimlane or lifeline which indicates a run-time instance of a process resource and its properties.

Provides an explicit connection between a locality or role in a behavior definition (a lifeline or swimlane) and a run time instantiation of a process, and optionally defines properties of the process. In some specifications there may be multiple deployment instantiations of the same process class, with different properties, so this stereotype should be used for the properties that are different.

Extensions

- NamedElement (from UML::Classes::Kernel)

Generalizations

- None

Associations

- None

Attributes

- poolSize: NFP_Integer [0..1] = 1
 the number of threads for the process.
- unbddPool: Boolean [0..1] = false
 indicates effectivelhy infinite threads if true.

- instance: MARTE::GRM::SchedulableResource [0..1]
the SchedulableResource which is the actual process resource.
- host: GaExecHost [0..1]
the host of the process and thus of all Steps associated with this run-time instance.
- utilization:NFP_Real [*]
the occupancy of the thread pool, in terms of the mean busy threads.
- throughput: NFP_Frequency [*]
the rate of acceptance of messages by all threads in the process, taken together.

Constraints

- None

17.3.2.14 SchedulableResource (from MARTE::GRM)

In performance modeling, a schedulable resource is a process or thread pool. A named element such as a swimlane or lifeline which represents behavior of a schedulable resource is stereotyped as a PaRunTInstance (see below) with a pointer to the resource, and also may capture the size of the thread pool and the host of the process.

17.3.2.15 PaStep

A step is a unit of a scenario. Some inherited properties of PaStep are given to provide performance interpretations. PaStep without a refining scenario is a basic sequential execution step on a host processor. With a refining scenario it is a larger unit of behavior.

Extensions

- None

Generalizations

- GaStep (from MARTE::GQAM)

Associations (inherited):

- behavior:GaScenario [0..1] a scenario which is a refinement of this Step.

Attributes (inherited)

- blockT: NFP_Duration [*]
a pure delay which is part of the execution of a step. Think times for performance models are represented by a blockT value.
- rep: NFP_Real [0..1] = 1
repetitions, used to represent loops or optional execution.
- prob: NFP_Real [0..1] = 1
probability of a branch.
- host: GaExecHost [0..1]
host processor (usually implicit in the deployment of the process).

- servDemand: GaRequestedService [*] {ordered}
a list of operations that are called during one execution of the Step.
- servCount: NFP_Real [*] {ordered}
a list of values for how many calls are made to each operation in the servDemand list, in the same order.
- concurRes: SchedulableResource [0..1]
the process or software component which executes the step, usually implicit in the location of execution in the behaviour definition (lifeline, swimlane).

Attributes

- noSync: Boolean [0..1] = false
identifying a Step immediately after a fork, for which there will be no corresponding join. An asynchronous branch of a fork.
- extOpDemands : String [*] {ordered}
a set of identifiers for operations by external services which are demanded by this Step, in a form understood by the performance environment.
- extOpCount: NFP_Real [*] {ordered}
the number of requests made for each external operation during one execution of the Step, in the same order as the demands.
- behavDemands: GaScenario [*] {ordered}
a set of scenarios defining operations which are invoked by this Step. This provides another way to insert a Scenario into a Step, in this case with a parameter for multiple, or probabilistic insertion.
- behavCount: NFP_Real [*] {ordered}
the number of requests made to execute each scenario operation during one execution of the Step, in the same order as the demands.

Constraints

- None

17.3.2.16 GaTimedObs (from MARTE::GQAM)

This observer stereotypes is a NFP_Constraint associated to two TimingObservations. In performance analysis it is used to identify and compute the duration of the time interval between them.

17.3.2.17 GaWorkloadEvent (from MARTE::GQAM)

Defines a stream of events that make up a workload which drives the system. For performance analysis the events can be taken from a trace (for simulation) from an arrivalPattern which can be an OpenPattern or a ClosedPattern, or from a WorkloadGenerator which is a State Machine defining sequences of operations.

17.3.2.18 GaWorkloadBehavior (from MARTE::GQAM)

A container for a set of Scenarios and a set of WorkloadEvents.

17.3.2.19 GaWorkloadGenerator (from MARTE::GQAM)

A State Machine defining sequences of events to drive a system. There may be a population of instances, each representing one user or one source of input.

17.4 Examples for Performance Analysis

17.4.1 Example 1: A Simple Web Application

The basic performance features will be illustrated by describing a web-based application. Example 1 is a simple sequential scenario with basic features of the profile: open arrivals, average processor demands, a repeated operation, multithreaded processes, and communication overheads at the nodes. Example 2 adds more complex behaviour patterns and corresponds roughly to a web application benchmark.

Figure 17.9, the blockT attribute of the LAN represents the network latency, and the capacity is the nominal maximum throughput rate. The send and receive overheads on the nodes apply equally to all transmissions. The nodes are stereotyped as ExecHost and each is a multiserver, with 5 and 2 processors respectively indicated by resMult (multiplicity of available instances). The webserver artifact represents a load module for the webserver and its deployment, and similarly for the database.

Figure 17.9 - Deployment of Example 1, with communications overhead annotations

Figure 17.10 - Example of interaction performance annotations

In Figure 17.10 a simple sequence is annotated, in which a web server makes calls to a database server. The Process annotation indicates the process resource with 80 threads, and links it to the webserver artifact deployed on the AppHost Node. Thus the host for PaSteps on this lifeline is the AppHost Node. The scenario steps are annotated on the messages, as the tool would not accept stereotypes for execution occurrences.

Walking through the message annotations, the first message is stereotyped with the workload, showing it has exponential inter-arrival times with a mean of 17 ms, thus it is a Poisson process with mean rate $1000/17 = 58.8/\text{sec}$. This is how a Poisson process must be annotated. It is also stereotyped as a PaStep with a hostDemand of 4.5 ms; this applies to the operation triggered by the message.

Message 2 is stereotyped both with the message size (in the CommStep stereotype) and the database operation parameters (in the PaStep). The Step is repeated an average of 1.3 times (from the repetitions attribute), and this implies the same for its invocation message, so the communication overhead demands and latencies are repeated also. The CommStep shows a small (2 KB) message, which according to the deployment information will generate:

host demand on AppHost of $1.3 * 2 * 0.1 = 0.26 \text{ ms}$

latency of $1.3 * 10 \text{ us}$

host demand on DBhost of $1.3 * 2 * 0.14 = 0.364 \text{ ms}$

The PaStep has an average of 1.3 repetitions, that is, it is performed conditionally and may be repeated, and creates a total of $1.3 * 12.4 = 16.12$ ms of demand for DBhost. The reply CommSteps apply further load,

from database: $1.3 * 50 * 0.07 = 4.55$ ms on DBhost, $1.3 * 50 * 0.15 = 9.75$ ms on AppHost

from webservice: $75 * 0.1 = 7.5$ ms on AppHost

and the recursive message 4 indicates an additional half ms demand for AppHost.

Performance Models: Queueing Network (QN)

A queueing model of this system has two servers - AppHost with 5 servers and total demand D_{ap} ms/request, and DBhost with 3 servers and total demand D_{db} ms/request - where:

$$D_{ap} = 4.5 + 0.26 + 9.75 + 7.5 = 22.01 \text{ ms/request}$$

$$D_{db} = 0.28 + 16.12 + 4.55 = 20.95 \text{ ms/request}$$

The annotations have not specified a message size for the original request from the browser, so it is ignored.

A QN model could be shown as follows:

Figure 17.11 - Queueing Network for Example 1

The two total demand values D_{ap} and D_{db} are sufficient to give a solution if this is assumed to be a separable QN, which means assuming processor-sharing scheduling at the two computers (not a very serious assumption for enterprise systems). The demands are assumed to include all operating system overheads, including background workloads. If additional workloads are present they should either be modeled as additional classes (from other scenarios) or some fraction of processor utilization should be allocated to them.

The QN model ignores the performance impact of the process thread pool sizes. To represent this we require an extended queueing network or layered network, that models the simultaneous possession of two resources (threads and processor). (see, e.g. Lavenberg, "Performance Modeling Handbook").

Extended Queueing Network or layered Queueing Network (EQN or LQN)

The ordinary queueing model ignores the thread limits on the webservice and database, which may limit performance. An EQN can model this with logical resources as shown in the Figure. The oval resource pools have resource tokens that are dispatched to requests in a queue (the upright triangle shows the dispatcher, the inverted triangle shows the release point for the thread).

Figure 17.12 - Extended Queuing Network diagram

The service time of the logical server is the holding time of the thread. Solution of an EQN is approximate, using various strategies (see eg, Jain, or Menasce and Almeida).

In this figure each process is a logical server with a queue and a pool of tokens representing the process threads. The arriving job just first obtain a process token and be processed by the webserver on AppHost, then without releasing the first token (since this is a blocking call) it obtains a database process token and be processed by the database on DBhost. It releases the second token and goes back with the reply to the webserver, cycles an average of 1.3 times to the database, and then releases the webserver token and departs. This resource logic is captured more compactly in the LQN, in which each process is a layered server, illustrated in Figure 17.12.

Figure 17.13 - Layered Queuing version of the same model

The LQN notation has servers which are processes or tasks (represented by the bold rectangles, with threading shown as a multiserver multiplicity) allocated to host processors, the ellipses, also with multiplicity. The classes of service are denoted as entries, the attached rectangles, showing the total hostDemand for each operation. Entries make requests to other entries, shown as arcs labeled with the mean frequency (1.3 here). The solution of the LQN is essentially the same as the solution of the EQN above, it is just a more elegant notation provided the usage of logical resources are nested, lower layers within higher.

17.4.2 Example 2: An Electronic Bookstore Home Page Interaction

This example illustrates additional annotations and their application to additional features of the UML2 Interaction Diagram:

- Parameters global to the AnalysisContext, and their use in expressions for values.
- Alt and par CombinedFragments stereotyped as Steps, with probability for alt.
- An external operation for storage.
- A noSync stereotype applied to an asynchronous operation.
- A closed workload.
- Computation of parameters for the reply to getHomePage, using an NFP with expressions to determine the value, depending on the variable \$images.
- A repeated action (getHomeImages) and an optional action with a probability.
- A percentile requirement on overall response time.

The example is elaborated from the Transaction Processing Council standard scalable benchmark TPC-W for electronic commerce (see TPC for the specification), by putting two Promotions into an alt combination (Promotion1 on the first pass, then Promotion2 thereafter), and introducing a logging operation in parallel with getHomeImages.

The scenario shows the interactions of a user starting from getting the home page, until the page is completely displayed. It includes checking the site's data on the user if the user is logged in with a site ID, retrieving a subpage on a promotion, getting page data from the database, and getting a number of embedded images from an image server.

The deployment is based on example 1, with an added image server. It does not specify the number of replicated processors, so the default value of 1 is assumed.

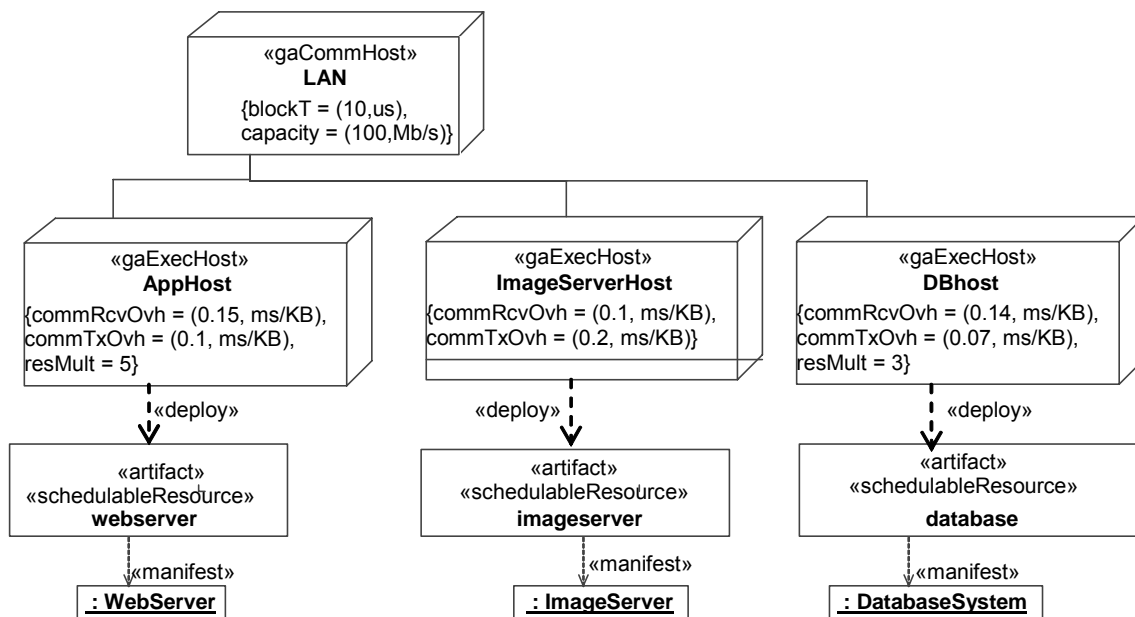

Figure 17.14 - Deployment of a web application representing the TPC-W benchmark

The behavior is shown in Figure 17.15.

Figure 17.15 - Example 2: the home page scenario of the TPC-W standard benchmark, with some additions to

illustrate alt and par CombinedFragments

17.4.3 Example 3: a building surveillance system

17.4.3.1 Overview

This is a soft real-time embedded system with a set of cameras that must be scanned at least once every second (with 95% probability), as described by Xu et al. The scan is free-running, with the next camera being polled as soon as the image-capture of the previous one is complete. The images are polled by an "acquire" thread, placed in a buffer and passed to a "storage" thread, which stores them in a database. Multiple buffers, asynchronous storage and multithreaded processes ensure concurrency in the handling, to obtain adequate performance.

The profile features which are emphasized in this example are

- case parameters attached to the PerformanceContext, giving the number of cameras (\$Ncameras), the size of a camera image (\$imageSize, in MB), and the number of storage blocks per image (\$blocks), with default values.
- annotation of an activity diagram, with process resources stereotyped on ActivityPartitions (swimlanes),
- repetition of a complex operation defined by a StructuredActivity. It is stereotyped as a Step with a repetition count and a refinement as the interior activity,
- use of both a mean and variance in defining a host demand parameter.
- a CommStep stereotype applied to an ActivityEdge
- a logical resource (the buffer pool) with multiple units, with explicit acquire and release steps.
- passing a resource from one process to another (passing a buffer to be stored),
- an external Service (a file storage operation) defined by name only in an extOpDemand attribute of the Database operation.

Figure 17.16 and Figure 17.17 show the deployment and activity diagrams for the example. In the deployment diagram the "SchedulableResource" stereotypes are shown only for the Control artifact, but in fact apply to all the artifacts shown (not shown to avoid diagram clutter).

Figure 17.16 - Deployment diagram of the building surveillance system of example 3

Examining the deployment diagram first, the nodes are stereotyped as ExecHost. As the Camera node is only symbolic, and is not represented in the design, it need not be stereotyped. The ProcessingRate attribute of the DataBaseNode is interpreted for performance as a factor, relative to a nominal processor, on which the hostDemand figures are based.

The deployed objects are all artifacts, and it is these artifacts that are referenced by the RunTInstance stereotypes in the activity diagram. The reference to the artifact (rather than to the class or instance) is to resolve the deployment of active objects. The bufferpool artifact stands for a set of buffers at run-time, and the number of buffers \$Nbuffers is a significant parameter for performance (remember resMult stands for "multiplicity of resource instances").

The attachment of the parameter \$Nbuffers to the analysis context assists in identifying parameters that may be varied over cases in the analysis. The analysis context should be shared with the behaviour diagram(s).

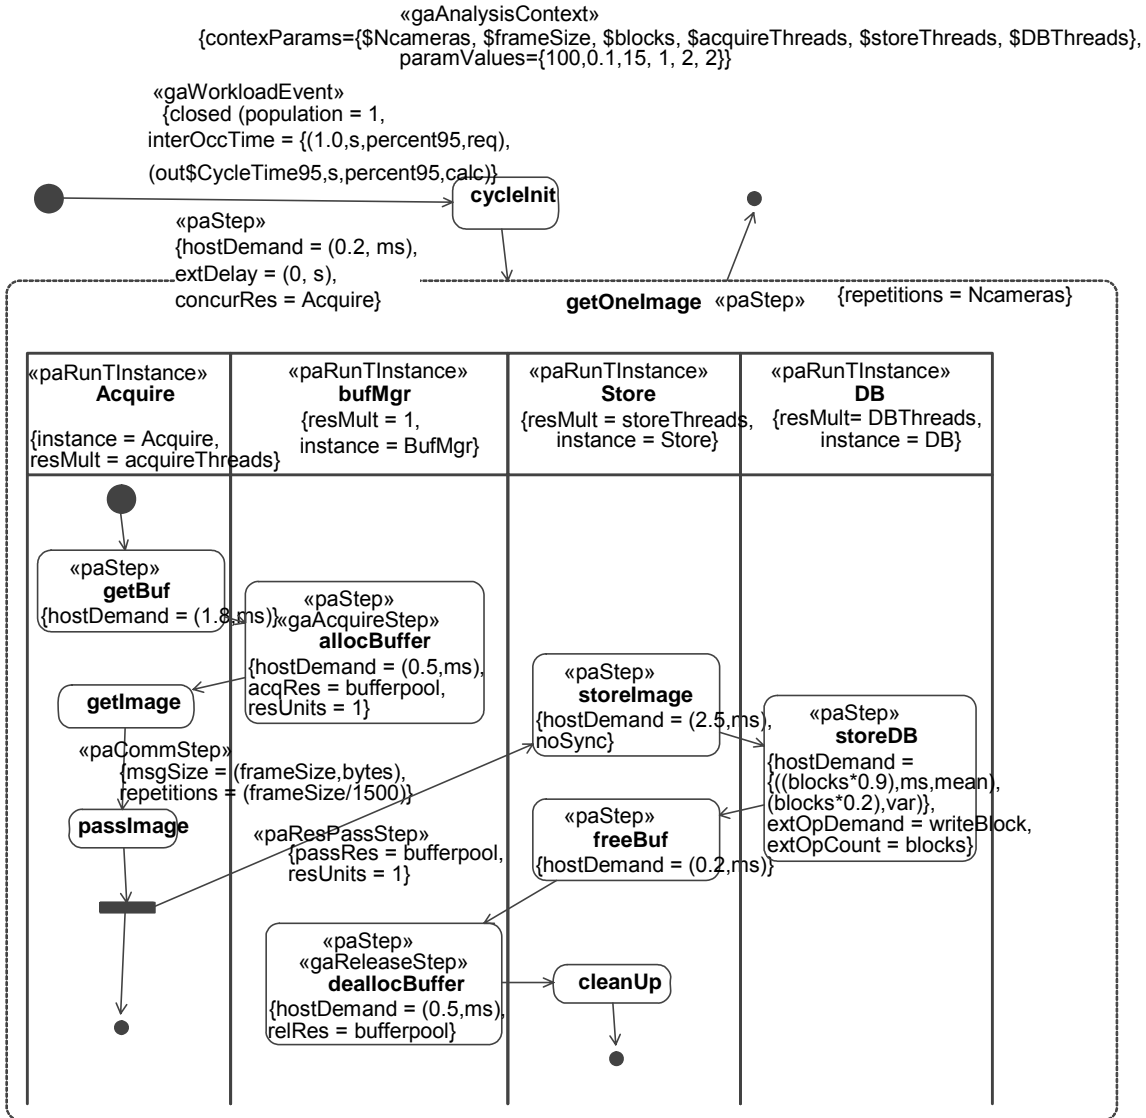

Figure 17.17 - Activity diagram for the building surveillance system of example 3

In the activity diagram there are additional global parameters associated with the analysis context. The workload is modeled as a single "user" (think of it as a token) which arrives to initiate a scan, and returns immediately after the scan is done, to start the next one. Thus the population is 1 and the external delay is zero. The performance requirement is on the 95th percentile of the time between successive initiations of the scan; thus 95% of scans should take less than 1 second.

The cycleInit Action has a hostDemand. Since it is not shown in a swimlane, its process (SchedulableResource) is given directly on the Step stereotype by the attribute "concurRes" (which determines its deployment and thus its host processor).

Apart from the scan initialization, the scan is a loop which is described inside a StructuredActivity which is stereotyped as a Step, with a repetition count equal to the number of cameras. Four processes are identified: the component attribute gives the artifact for deployment, and the resMult attribute gives the number of threads. Two comments:

- Since threads are annotated on the paProcess, two run-time instantiations of the same artifact can have different numbers of threads.
- One artifact may manifest multiple processes.

The StructuredActivity has two ending points, and shows the use of the noSync attribute of the storeImage Step, to enhance concurrency. After the fork node on the left, the main loop ends and this allows the next iteration to begin. The explicit noSync attribute on the storeImage action shows that the main behaviour does not wait for this branch to complete, so the right-hand behaviour for storing the frame continues in parallel with the next scan. In fact, the concurrency of the storage behaviour is only limited by the number of Store threads and the number of buffers. This overlapped storage behaviour is illustrated by a Gantt chart, in Figure 17.17. Any number of concurrent storage operations can be continuing while further buffers are filled, up to the point where there are no free buffers to allocate.

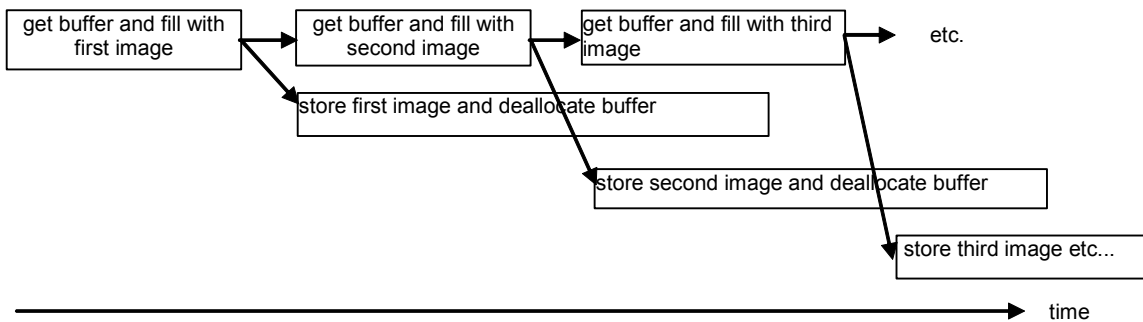

Figure 17.18 - An asynchronous pattern of buffer storage operations, indicated by the noSync property (to indicate concurrent continuation of a refinement BehaviorScenario after the return to the outer level of behaviour).

The bufferpool logical resource is of importance in this specification, as the system suffers easily from buffer starvation. Notice:

- The number of buffers is declared on the deployment artefact.
- The acquisition and release of the buffers are separate stereotypes on the buffer manager steps which allocate and deallocate them. The single unit of resource is shown explicitly on the allocate (it need not be defined as one is the default), but the deallocate uses the default.
- The explicit passing of the buffer from one process to another is shown by the ResourcePassStep stereotype attached to an ActivityEdge from Acquire to Store. Here the unit is shown (one is again the default). Without an explicit ResourcePassStep, the logical resource is handed on along the flow, including flows that cross from one process to another (as in the return from the Buffer manager). However after a fork in the flow it may be essential to indicate the passing explicitly.

Only one CommStep is annotated here, for the delay to transfer the data over the network. The database communications might also be significant. The annotations give a derived communications latency of (message size)/rate, in the absence of explicit delay and demand attributes in the deployment diagram.

The use of mean and variance in specifying a random hostDemand, is illustrated for the storeDB action. Notice that the units are not given for the variance (implicitly they are the square of the units for the mean, but they are normally not stated).

An external operation is defined for the storeDB action, defining the storage on disk of one block of image data, with an operation count of \$blocks.

17.4.4 Example 4: communications example, a layer subsystem

Communications is provided by the execution platform of the system, and this may be described in UML by a layering of components and subsystems. The commService stereotype on a message identifies an Operation on an interface of the platform, as conveying the message. This section illustrates the concept with an oversimplified CORBA layer submodel.

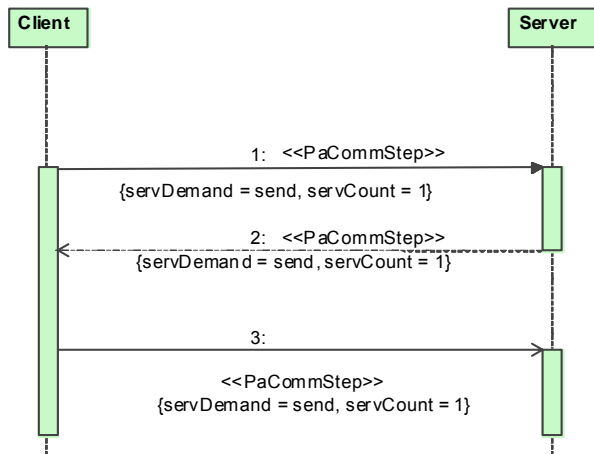

Figure 17.19 - Sending of messages by the application, with commService attributes

Figure 17.18 shows a call-reply pair and an asynchronous message. Notice that the reply is stereotyped separately here, so it has its own sub-scenario. It is also possible to aggregate all the latencies and workloads into the request, which provides the correct total workload and delays but does not represent the behaviour precisely. Figure 17.19 shows the simplified CORBA system, with a stub component (integrated with the sender), a skeleton component (integrated with the receiver), an ORB component to execute the core functions, and a location server. The last two are separate processes in this assumed system; the deployment will not be shown.

Figure 17.20 - A simplified CORBA layer subsystem

The send port has an interface of type Sending which offers an operation send, which is stereotyped as a "paRequestedService", with behaviour definition given by the sequence diagram in Figure 17.21 (the behaviour attribute does not show in the stereotype).

The identification of the send operation of the layer, in the commStep stereotype, binds the CORBA layer component model that offers this service, and the behaviour model, into the original scenario. The send operation that starts the scenario in Figure 17.21 is the operation that begins the conveyance of the message. The binding of the receive required interface and the receive operation of Figure 17.21 to the receiver of the application message is implicit.

SD corbaSend «gaScenario»

«gaAnalysisContext» {contextParams=in\$messageSize}

Figure 17.21 - Behavior of the operation "send"

17.4.5 Example 5: services by component subsystems

Operations by components and subsystems may be included in a Step by giving it an attribute servDemand with a parameter servCount. ServDemand is typed on the operation, which itself must be stereotyped as GaRequestedService, and servCount is the average number of invocations. Services may be useful to include platform and environment operations, without modifying the behaviour definition provided by the designer.

Figure 17.22 shows a basic behaviour that invokes a findRecord operation defined on the class DataManager, three times. The findRecord operation is shown in Figure 17.23 and is annotated with its hostDemand and an external service operation.

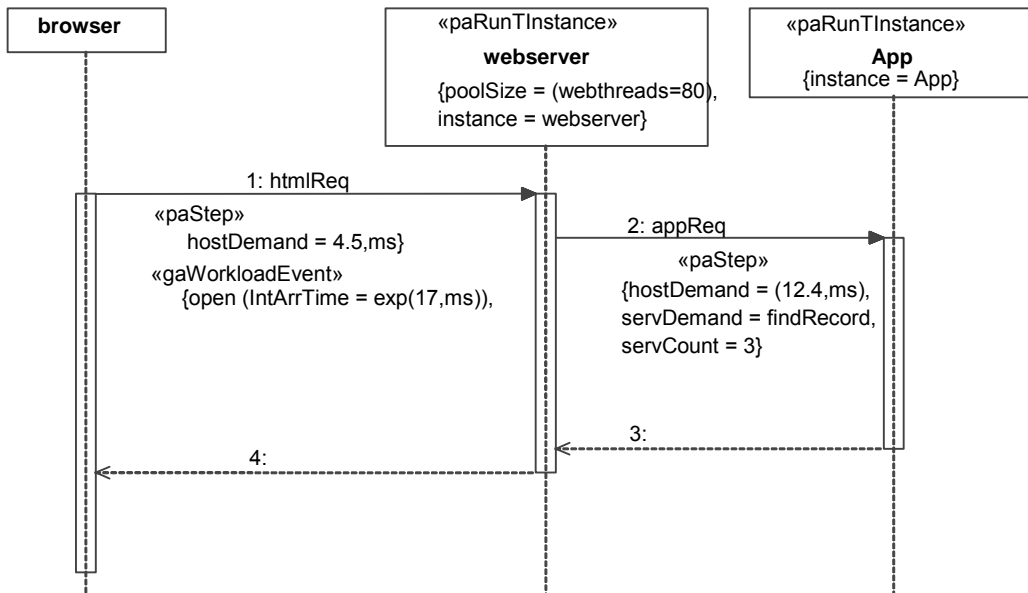

Figure 17.22 - Sequence diagram for an operation findRecord invoked from a Step

Figure 17.23 - The DataManager class with annotated operation findRecord

In both Figure 17.21 and Figure 17.22, the operation findRecord is stereotyped on the DataManager class, not on a runtime instance of DataManager. Because the stereotype extends PaStep, it can also have properties execHost and concurRes which identify the host processor and process, respectively. This is sufficient if there is just one deployment of DataManager. If there is more than one deployed instance of DataManager, there is a problem to identify which instance is invoked and what are the parameters such as hostDemand. A possible solution is to use a different variable name for the servCount in the PaStep stereotypes that make the invocations. Then that variable name can be associated with a deployed instance in a table.

For example if StepA invoked findRecord on dataManager1 its servCount for the operation could be set to the variable \$findR1, while StepB invokes the same operation on dataManager2 \$findR2 times. Then a table can be set up:

Table 17.1 - Instance Parameters for calls to DataManager findRecord

Instance	servCount Variable	Value
dataManager1	\$findR1	3
dataManager2	\$findR2	1.7

This associates the instances with the Step and a value. The tool would have to determine the deployment of each instance by name, however.

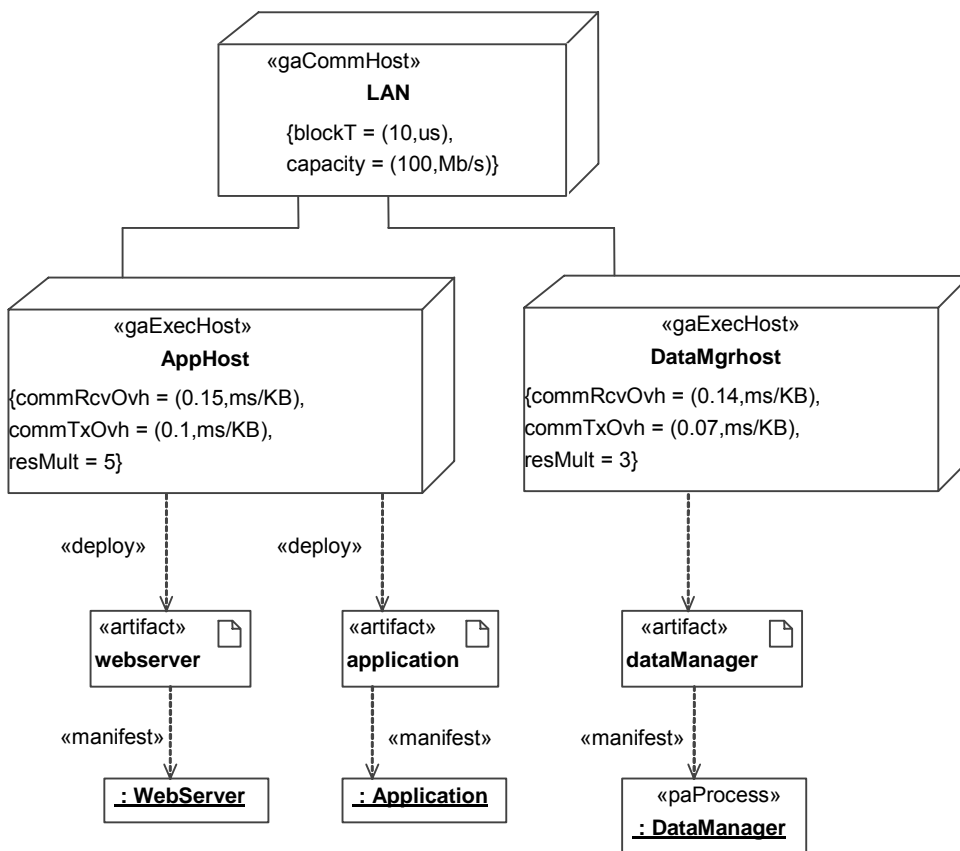

Figure 17.24 - Deployment of the dataManager instance of DataManager

Call Hierarchy

The operation findRecord may be the work of a subsystem rather than a single object, and the subsystem can be annotated to show the invocation hierarchy and to parameterize the calls. The next example shows a call hierarchy and also a number of instances of the same class, with additional parameters. The call hierarchy may be represented schematically in terms of the instances as Figure Figure 17.25, with a modified data manager DataManagerB.

Figure 17.25 - (a) Call Hierarchy for the findRecord operation of DataManager, (b) Class structure of the call hierarchy

First the class structure of the call hierarchy may be represented as in Figure 17.25(b). The operations of the classes are annotated to represent this, with variables for the operation counts, in Figure 17.26.

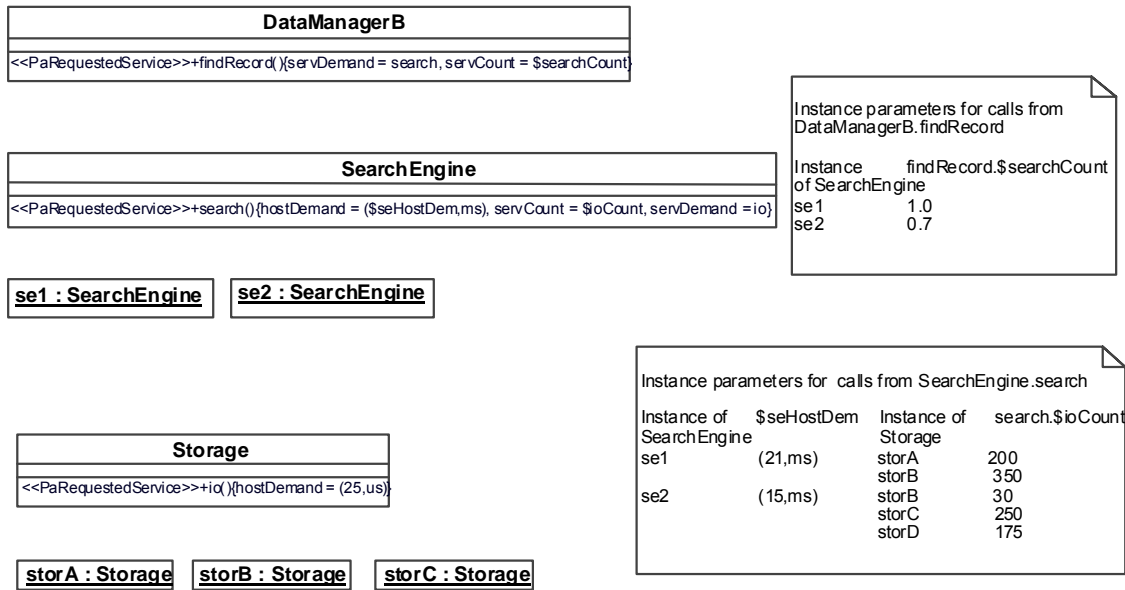

Figure 17.26 - Annotations to the classes for the class invocation hierarchy of Figure 17.25

We can see in the annotations that the target operations are identified, with variable \$searchCount for the search operation and variable \$ioCount for the io operation. The bindings of instances to invocations is defined in the tables. In the upper table it is stated that there are calls to two different instances of SearchEngine, with the given values of the count. Notice that since it is an average count it can be non-integral. These values are NFPs so it could be written with a statistical qualifier.

In the lower table the instances of SearchEngine and Storage are bound together by definitions of the \$ioCount variable for different combinations of the calling and called operation, and the parameters \$seHostDem of the search operation is defined for each instance of SearchEngine.

17.4.6 Example 6: state machine annotations

We will consider some kinds of behaviour described by a state machine. The first kind will be a state machine that governs the generation of requests, called in the profile a "Workload Generator" state machine. The states represent states of the user (or the process that generates the workload) and in each state, there is a reference to a behaviour for that state. This behaviour represents an action taken on entering the state. The `blockingTime` attributes represent user-thinking time during that state, before the user enters the request that will take it to a new state.

Figure 17.27 shows a simplified version of the cycle of user states described for the TPC-W benchmark, and references one interaction diagram in each state. The behaviour for each state is a single execution and does not itself have repetitive workload attributes. The `getHomePage` interaction diagram would be the same as the one depicted in Figure 17.15 but its `GaWorkloadEvent` stereotype would reference the state machine as a `WorkloadGenerator`.

```

«gaAnalysisContext» {contextParams=(in$Nusers)}
«gaWorkloadGenerator» {population=iNusers}

```

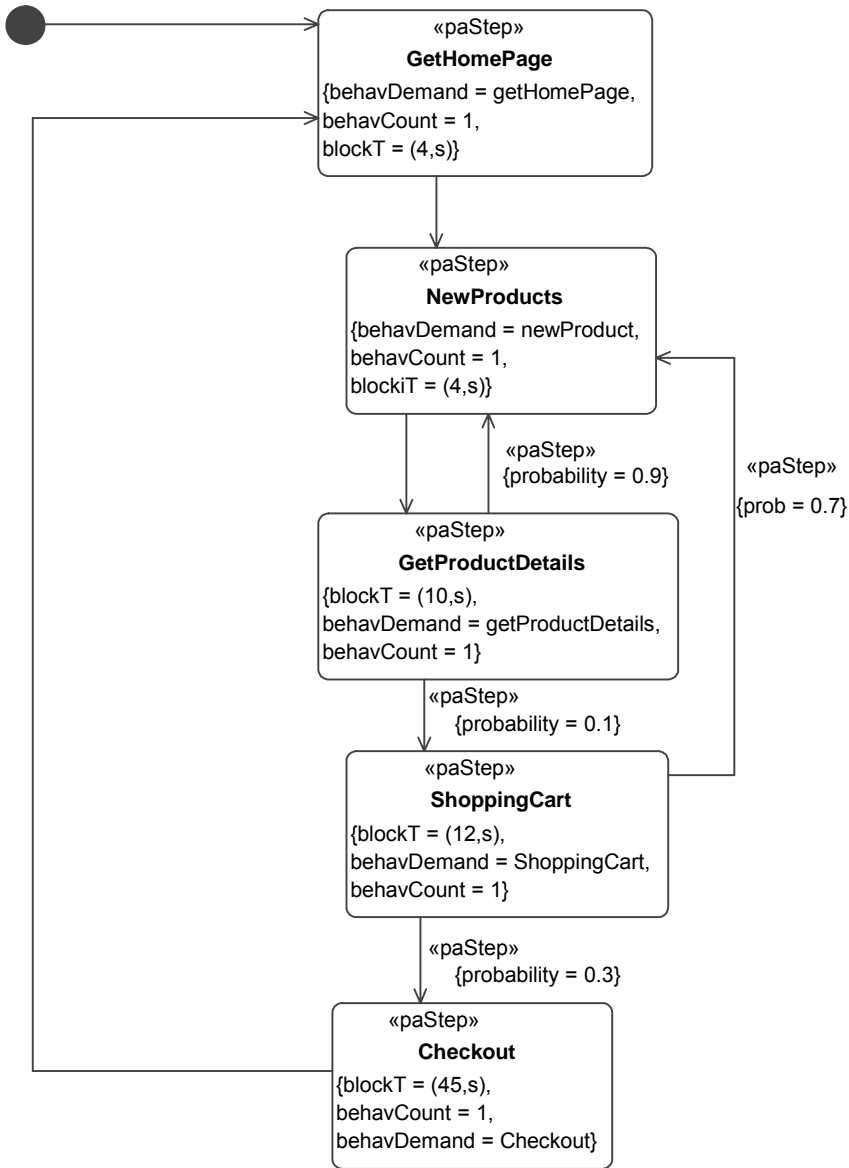

Figure 17.27 - Example 6: a WorkloadGenerator state machine combining five scenarios for the electronic bookstore

Some of the transitions are also annotated as PaStep in order to specify the transition probability. to the next state. For instance after GetProductDetails, there is specified a 90% probability of looking for new products again, and 10% for proceeding to the shopping cart.

A workload generator could more generally be a set of state machines communicating by signals and all generating behaviour concurrently.

The analytic performance model will represent the generator as a Markov Chain governing the probabilities of making requests for different behaviours (what is sometimes called the user profile).

The Markov Chain is solved to provide the steady state probabilities of each state, and thus of each behavior in the combined workload.

A second use of a state machine is to define a sequence of operations, like an interaction diagram. This must be a behaviour that terminates, and its start point is driven by a RequestEventStream. Each state or transition can be an PaStep, and a state can be refined to a subscenario either as a composite state or by an annotation with a behavDemand as above. A composite state with multiple regions is an implicit parallel section, however all the details of composite states (e.g. history) have not been integrated into the profile. This kind of terminating behaviour can also be defined with several interacting machines.

A third use of a state machine is similar to the second, but it repeats infinitely, waiting at some well-defined "home state" for in input events derived from a WorkloadEvent stream.

Part IV - Annexes

This Part contains the following annexes.

- A - Guidance Example for Use of MARTE
- B - Value Specification Language (VSL)
- C - Clock Handling Facilities
- D - Normative MARTE Model Libraries (MARTE_Library)
- E - Repetitive Structure Modeling (RSM)
- F - Domain Class Descriptions
- G - Bibliography
- H - Mapping SPT on MARTE

Annex A: Guidance Example for Use of MARTE

A.1 Open-source Tool Support for MARTE

In the context of different projects - System@tic::UsineLogicielle::OpenDevFactory (<http://www.usine-logicielle.org/>), RNTL::OpenEmbeDD (http://openembedd.inria.fr/home_html) and CARROLL::Protes/CORTESS(<http://www.carroll-research.org/>) - the CEA LIST has developed an open-source implementation of the UML profile for MARTE (including a support for the VSL language). This implementation is an eclipse-based project and it is available at this address: www.papyrusuml.org.

A.2 AADL-like models with MARTE

We consider here the correspondence in MARTE of some of the basic AADL concepts, as found in the SAE standard AADL summary (SAE AS-5506/1):

An AADL specification consists of AADL global declarations and AADL declarations. Global declarations essentially describe a hierarchical package structure for the system model.

AADL declarations comprise component types and implementations and port group types.

A component type specifies a functional interface in terms of "features", flow specifications and properties. These would be considered as communication models in MARTE.

A component implementation describes the internal structure and behavior of that component in terms of subcomponents, connections and flows across them, and behavioral modes,

A system modeled in AADL consists of "application software" components "bound" to "execution platform" components. In MARTE the word "software" is dropped from "application", since the execution platform can also contain software (middleware, RTOS,...) as well as hardware parts. AADL "binding" is called "allocation" in MARTE, following the SysML wording, but the concept is the same. It can be hierarchical and compositional.

AADL application 'software' components are made of data, threads, and process components. Data are akin to Objects in UML, as they may contain "subprograms", similar to UML operations. AADL thread components model units of concurrent execution. A scheduler manages the execution of a thread. Threads can be in states such as suspended, ready or running. State transitions occur as a result of dispatch requests [...] or if time constraints are exceeded. Dispatch semantics are given by standard dispatch protocols such as periodic, sporadic and aperiodic threads. Additional dispatch protocols may be defined. This provides various models of computation, including simultaneity of concurrent threads running periodically on the same clock. Different clock domains can be defined; as well as explicit delays on any logical clock. This again is in line with some of MARTE's requirements. Threads owe behaviorally to UML activity diagrams, which allow distinction between Object (Data) and Control (Event) flows.

AADL execution platform components use processors, memory, busses and devices. They are connected by "features" such as flows and may be structurally and behaviorally switching modes (in a control-flow fashion). This again is in line with MARTE. Flows can be represented by UML sequence diagrams, and modes by state diagrams.

Operating systems may be represented through properties of the execution platform or, requiring significantly more detail, modeled as software components. These calls for various Models of Computation, and the ability to model in the RT/E design part the scheduling disciplines considered in the Analysis part is also a goal in MARTE.

An AADL system design contains a set of properties needed to support system generation and/or desired forms of scheduling analysis. This information will be generated from the AADL design model.

A.2.1 MARTE for AADL Summary Table

AADL concept	MARTE/UML concept for design	MARTE/UML concept for analysis	AADL definition
Software component			
Process	MARTE <i>memoryPartition</i> stereotype on UML Classifier	NA	Represents a protected address space and contains executable code or data.
Thread	MARTE <i>swSchedulableResource</i> stereotype on UML Classifier	NA	Concurrent schedulable unit of sequential execution through source code
Thread Group	MARTE abstract <i>SwSchedulableResource</i> stereotyped UML classifier composed of <i>swSchedulableResource</i> stereotyped UML classifiers which are not abstract	NA	Component abstraction for logically organizing thread, data and thread group component within a process
Shared Data	<i>SwMutualExclusionResource</i> stereotype on UML classifier	Marte <i>SwMutualExclusionResource</i> stereotype on UML classifier	For analysis purpose, the associated to <i>RealeaseService</i> ” and <i>AcquiredServices</i> stereotype attributes will point towards “read” and “write” operations, which could be respectively stereotyped <i>GaAcqStep</i> and <i>GaRelStep</i> for analysis purposes
Data access via interface	“Resource”, “ConcurrencyResource”, “ProcessingResource” concepts of GRM depending on the user’s precision requirements. Can be refined with SRM equivalent concepts “swConcurrencyResource”, etc	NA	
Subprogram	UML Operation	NA	Represents sequentially executable source text
Subprogram Calls	UML Operation call on sequence diagrams. For software platform design, can be model as “messageComResource”	“SaStep”	Access to a callable method or a server service with a declaration within a subprogram implementation or a thread
Server subprogram	“entryPoint” stereotype dependency between “SwSchedulable Resource” and called UML Operation	NA	

AADL concept	MARTE/UML concept for design	MARTE/UML concept for analysis	AADL definition
Execution platform components			
Processor	<i>hwProcessor</i> stereotype on UML Classifier	NA	Hardware unit responsible for scheduling and executing threads.
Memory	<i>hwMemory</i> stereotype on UML Classifier	NA	Abstract representation which is a storage component for data and executable code
Bus	<i>HwBus</i> stereotype on UML Classifier	NA	Hardware unit that enable communication among other execution platform components
Device	<i>hwDevice</i> stereotype on UML Classifier	NA	Represents entities that interfaces with the external environment of an application system

AADL concept	MARTE/UML concept for design	MARTE/UML concept for analysis	AADL definition
System composition			
System	UML <i>systemModel</i> stereotype	NA	Represents a composite software, execution platform or system components

AADL concept	MARTE/UML concept for design	MARTE/UML concept for analysis	AADL definition
Features and shared access			
Port	<i>flowPort</i> or <i>msgPort</i> stereotyped UML Port	NA	Represents a communication interface for the directional exchange of data, event or both between components
PortGroup	Composite interface stereotyped by both <i>FlowSpecification</i> and <i>BfeatureSpecification</i> stereotypes typing ports stereotyped by <i>MsgPort</i> and <i>FlowPort</i>	NA	Represents a collection of port group or port
Inverse of	<i>IsConjugated</i> stereotyped attribute on “FlowPort” and “Msg Port” UML ports		
Subprogram as Features	UML Operation	NA	Represents sequentially executable source text
Subprogram Parameters	UML Parameters	NA	Represents the subprogram parameters
SubComponent Access	Data or Bus access via specific UML interfaces	NA	Explicit data or bus access

AADL concept	MARTE/UML concept for design	MARTE/UML concept for analysis	AADL definition
Connections and flows			
Port Connections	UML delegation connectors between Ports and Parts on composite diagrams	NA	A connection declaration binds a port from a component to another
Parameter Connections	ObjectFlow on UML activity diagram	NA	Used when a subprogram output need to be link with an entry point of an other subprogram
Access Connections	UML connections between UML ports requiring specific data access to data interface	NA	Access connections designate access to shared data components
Flows specifications	UML Object Flow between UML Object Pins in an Activity Diagram	NA	Specifies the detailed description and analysis of an abstract information path throughout a system
End-To-End Flows	NA	MARTE “End2EndFlow” represented in activity diagram to ensure hierarchical flow path representations	Specifies a flow that starts within one subcomponent and ends within another.

AADL concept	MARTE/UML concept for design	MARTE/UML concept for analysis	AADL definition
Properties			
AAD property set	MARTE stereotypes and associated attributes and user defined <i>Nfp</i> pstereotyped attributes.	MARTE stereotypes and associated attributes and user defined <i>Nfp</i> stereotyped attributes.	

AADL concept	MARTE/UML concept for design	MARTE/UML concept for analysis	AADL definition
Operational modes			
Mode	Mode as UML StateMachines; mode specific port connections are described with UML Collaborations.	NA	Represents a defined configuration of contained components, and connections

AADL concept	MARTE/UML concept for design	MARTE/UML concept for analysis	AADL definition
Operational system			
System Binding	MARTE <i>allocation</i> stereotyped UML Dependency, with attribute “nature” set to “SpatialDistribution”	NA	Binds software components to appropriate execution platform components (i.e. hardware components)

AADL concept	MARTE/UML concept for design	MARTE/UML concept for analysis	AADL definition
Component relationship			
Component extension	UML Generalization	NA	
Component implementation	UML Realization	NA	

A.2.2 Packages, components declaration and implementation

A.2.2.1 Packages

AADL packages will be used to organize component modeling, improving model lisibility and component reuse. AADL packages will be modeled by the way of UML packages as shown Figure .

A.2.2.2 Component type and implementation

In AADL, each component is characterized by a component declaration and some component implementation descriptions. Each component type specifies the external behavior of the component, its way of communicating and features that might be provided for other elements. Component implementations allow the definition of subcomponents, mode specific behaviors or components properties.

Component declarations and implementations could be modeled in different packages named Declaration and Implementation as shown Figure . A UML Realization will be used to formalize this implementation relationship ("Gps" component can have two different implementations named "Gps.Basic" and "Gps.Handheld"). Component declaration and implementation could also be extended using a UML Generalization link ("Gps.Handheld" implementation extends "Gps.Basic" implementation)

Figure A.1 - Component Types and Implementation modelling

A.2.3 Software Components

A.2.3.1 Process

A process represents a virtual address space that protects its internal data. This virtual address space contains the program formed by the source text associated with the process and its subcomponents. It can access to external data through server subprograms or data reference. A single process does not contain an implicit thread. In many cases, a processor will be bound to a process via a specific binding link.

Table A.1 - Component and Associated Features Representation

AADL Concept		UML profile
Process		UML classifier stereotype by the MARTE «partitionMemory» stereotype

Table A.1 - Component and Associated Features Representation

Type	Provide data access, Require data access	UML Realization / UML Dependency between the process and data Interface
	Port	MARTE Flow Port
	Server subprogram	«server_subprogram» stereotyped UML Dependency between server components and the called subprogram (UML Operation)
	Flow specification	UML Flows and UML Pinss on Activity diagrams
	Properties	UML::Comment stereotyped with «AADL_Properties»
Implementation	Subcomponent (data, thread, thread group)	UML Part of the owner component
	Connections	UML Connector and delegation connectors between Ports in composite structure diagram
	Flows	UML Flows and UML Pinss on Activity diagrams
	Modes	UML Collaboration and UML State Machines
	Properties	UML::Comment stereotyped with «AADL_Properties»

<i>AADL properties</i>	<i>Marte Design</i>	<i>Marte SW/HW platform</i>	<i>Marte Analysis</i>
Scheduling_protocol	NA	NA	Specified by the “schedPolicy” attribute of <i>Scheduler</i> stereotype
Ex: EDF, RMS, SporadicServer, SlackServer, ARINC653			<i>Scheduler</i> and <i>SchedulableResource</i> stereotypes modeling with associated scheduling policy kinds, and scheduling parameters.
load_time and load_deadline			Specific “execTime” and “deadline” attributes from <i>SaStep</i> stereotype corresponding to operations defined in the Swplatform model
Period and deadline are specified for inheritance			Period and deadlines are specified at the thread level on WorkloadEvent and SaSteps.

An AADL process will be represented by a MARTE "partition Memory" stereotyped UML classifier, containing subcomponents as UML parts, communicating with other components or subcomponents through ports. In the following example, the "control_processing.speed_control" process contains four subcomponents.

```

process implementation control_processing.speed_control
subcomponents
    control_input : thread control_in.input_processing;
    control_output : thread control_out.output_processing;
    control_thread_group : thread group control_threads.control_thread_set;
    set_point_data : data set_point_data_type;
end control_processing.speed_control

```

Figure A.2 - AADL Process example

Figure A.3 - Process and contained subcomponents UMLrepresentation

A.2.3.2 Thread

A thread is a concurrent schedulable unit of a sequential execution through source code. A thread models a schedulable unit that transits between various scheduling states. It always executes within the virtual address space of a process, i.e. the binary images making up the virtual address space must be loaded before any thread can execute in that virtual address space.

Component and associated features representation

AADL Concept		UML Profile
Thread		«swSchedulableRessource» stereotyped UML class
Type	Provide/require	UML Dependency or UML Realization between the thread and the data associated Interface.
	Port	MARTE Flow Port
	Port Group	«port_group» stereotyped UML Classifier
	Server subprogram	«server_subprogram» stereotyped UML Dependency between server components and the called subprogram (UML Operation)
	Properties	UML::Comment stereotyped with «AADL_Properties»
	Flow Specification	UML Flows and UML Pinns on Activity diagrams

Implementation	Subcomponents (data)	UML Part of the owner component
	Subprogram Call	UML Message in UML Sequence diagrams
	Connections	UML Connector and UML delegation Connectors between Ports in composite structure diagram
	Flows	UML Flows and UML Pins on Activity diagrams
	Modes	UML Collaboration and UML State Machines
	Properties	UML::Comment stereotyped with «AADL_Properties»

<i>AADL properties</i>	<i>Marte Design</i>	<i>Marte SW/HW platform</i>	<i>Marte Analysis</i>
Dispatch protocol: enumeration	NA	NA	Specified at the WorkloadEvent concept triggering the SaScenario
Periodic			“PeriodicPattern” enumeration literal selected for “Pattern” attribute for the WorkloadEvent stereotype
Sporadic			“SporadicPattern” enumeration literal selected for “Pattern” attribute for the WorkloadEvent stereotype.
Aperiodic			“AperiodicPattern” enumeration literal selected for “Pattern” attribute for the WorkloadEvent stereotype
Background			New issue raised
Period: Time			“Period” attribute from the “PeriodicPattern” attribute specified by the WorkloadEvent stereotype
Deadline: Time (inherited from period)			At this level, the same as “Period” attribute defined above
Compute_execution_time			Computed from the different “Steps” concepts supported by the thread; shall be defined in scenarios
Compute_deadline			Computed from the different “SaSteps” supported by the thread; shall be defined in scenarios
Initialize_execution_Time and Initialize_deadline			Specific “execTime” and “deadline” attributes from SaStep stereotype corresponding on mode switch operations defined in the SwPlatform model
Active_execution_time (specific for mode switch) and Active_deadline (specific for mode switch)			Specific “execTime” and “deadline” attributes from SaStep stereotype corresponding on mode switch operations defined in the Swplatform model

Deactive_execution_time (specific for mode switch) and Desactive_deadline (specific for mode switch)			Specific “execTime” and “deadline” attributes from <i>SaStep stereotype</i> corresponding on mode switch operations defined in the Swplatform model
Recover_execution_time (specific for mode fault handling) and Recover_deadline (specific for mode fault handling)			Specific “execTime” and “deadline” attributes from <i>SaStep stereotype</i> corresponding on mode switch operations defined in the Swplatform model
Finalize_execution_time and Finalize_deadline			Specific “execTime” and “deadline” attributes from <i>SaStep stereotype</i> corresponding on mode switch operations defined in the Swplatform model
Synchronized_component			<i>Nfp</i> stereotyped attribute defined by the end-user
Active_thread_handling_protocol (specific to mode switch): ex abort, complete_one_flush_queue, complete_one_transfer_queue, complete_one_preserve_queue, complete_all			<i>Nfp</i> stereotyped attribute with associated end-user defined enumeration

The following example illustrates a thread containing a data subcomponent.

```

thread control_laws
end control_laws;

data static_data
end static_data;

thread implementation control_laws.control_input
subcomponents
configuration_data : data static_data;
end control_laws.control_input;

```

Figure A.4 - AADL Thread example

Figure A.5 - Thread and data subcomponent UML representation

A.2.3.3 Thread Group

A thread group represents an organizational component to logically group threads (as well as their properties and features) contained in processes. The type of a thread group component specifies the features and required subcomponent access through which threads contained in a thread group interact with components outside the thread group. Thread group implementations represent the contained threads and their connectivity.

A thread group does not represent a virtual address space nor an execution unit. Therefore, a thread group must be contained within a process.

Component and associated features representation

AADL Concept		UML Profile
Thread group		«swSchedulableRessource_group» stereotyped UML class
Type	Provide data access	UML Dependency or UML Realization between the thread group component and the data associated Interface.
	Require data access	
	Port	MARTE Flow Port
	Port Group	«port_group» stereotyped UML Classifier
	Server subprogram	«server_subprogram» stereotyped UML Dependency between server components and the called subprogram (UML Operation)
	Properties	UML::Comment stereotyped with «AADL_Properties»
Implementation	Flow Specification	UML Flows and UML Pins on Activity diagrams
	Subcomponents (data, thread, thread group)	UML Part of the owner component
	Connections	UML Connector and delegation connectors between Ports in composite structure diagram

	Flows	UML Flows and UML Pins on Activity diagrams
	Modes	UML Collaboration and UML State Machines
	Properties	UML::Comment stereotyped with «AADL_Properties»

The following example illustrates a thread group containing threads and data components.

```

thread group control
properties
Period => 50 ms;
end control;

thread group implementation control.roll_axis
subcomponents
control_group : thread group control_laws.roll;
control_data : data data_control.primary;
error_data : data data_error.log;
error_detection : thread monitor.impl;
end control.roll_axis;

thread monitor
end monitor;

thread implementation monitor.impl
end monitor.impl;

data data_control
end data_control;

data implementation data_control.primary
end data_control.primary;

data data_error
end data_error;

data implementation data_error.log
end data_error.log;

thread group control_laws
end control_laws;

thread group implementation control_laws.roll
end control_laws.roll;

```

Figure A.6 - Thread Group AADL example

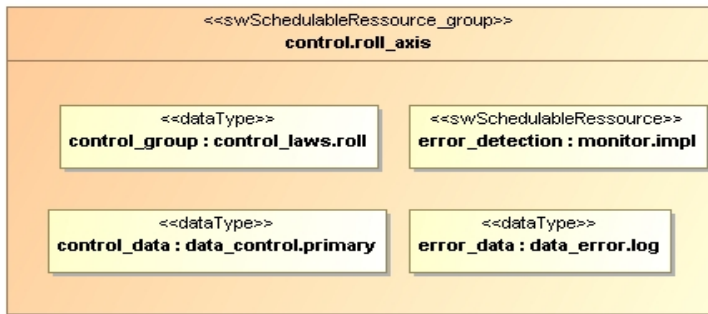

Figure A.7 - Thread group and subcomponents representation

A.2.3.4 Data

The data abstraction represents static data and data types within a system. Specifically, data component declaration are used to represent:

- Application data types.
- The substructure of data types via data subcomponents within data implementation.
- Data instances.

Component and associated features representation

AADL Concept		UML Profile
Data		UML::DataType
Type	Provide data access	UML Realization between the data component and its interface
	Subprogram	UML Operation of a UML Class
	Properties	UML::Comment stereotyped with 'AADL_Properties ^a
Implementation	Subcomponents (data, thread, thread group)	UML Part of the owner component or UML attributes for primitive types
	Connections	UML Connector and delegation connectors between Ports in composite structure diagram
	Modes	UML Collaboration and UML State Machines
	Properties	UML::Comment stereotyped with 'AADL_Properties ^a

<i>AADL properties</i>	<i>Marte Design</i>	<i>Marte SW/HW platform</i>	<i>Marte Analysis</i>
Shared data aspect	<i>MutualExclusionResource</i> stereotype	<i>swMutualExclusionResource</i> stereotype	<i>swMutualExclusionResource</i> stereotype
Concurrency_Control_Protocol: enumeration	NA		<i>concurrentAccessProtocol</i> stereotype attribute
Priority_Inheritance			"PIP" enumeration literal of "ConcurrentAccessProtocol-Kind" enumerate
Interrupt_Masking			New issue raised
Priority_Ceiling			"PCP" enumeration literal of "ConcurrentAccessProtocol-Kind" enumerate
Maximum_Priority			New issue raised
Data access via interface	<i>Resource, ConcurrencyResource, ProcessingResource</i> of GRM depending on the user's precision requirements	Associated SRM equivalent concepts i.e. <i>swConcurrencyResource</i> , etc	

Data types information may be required from other components. To provide this data access service, the UML interface semantics is used. Each data will realize an interface providing access to data internal information; external components will require access to this interface (data access is detailed section A.2.6.3).

The following example illustrates the "address.other" data component containing four data components. As these subcomponents are primitive types, they are represented as attributes of the address.other data component. Moreover, the "address.other" data component provides access to street, street number, city and zip code information through the "address_interface" it realized.

```

data address
end address;

data implementation address.other
subcomponents
street : data string;
streetnumber : data int;
city : data string;
zipcode : data int;
end address.other;

data string
end string;

data int
properties
Source Data Size => 64b;
end int;

```

Figure A.8 - Data UML representation

A.2.3.5 Subprogram

A subprogram represents a sequentially executable source text, a callable component with or without parameters that operates on data or provides server functions to components that call it.

Component and associated features representation

AADL Concept		UML Profile
Subprogram		«subprogram» UML Operation on UML class representing a Library
Type	Require data access	UML Dependency between the subprogram and the data provided Interface
	Port	MARTE Flow Port
	Port Group	«port_group» stereotyped UML Classifier
	Parameter	UML Operation Parameters
	Flow specifications	UML Flows and UML Pins on Activity diagrams
	Properties	UML::Comment stereotyped with «AADL_Properties»
Implementation	Connections	UML Connector and delegation connectors between Ports in composite structure diagram
	Subprogram Call	UML Message on UML Sequence diagrams
	Flows	UML Flows and UML Pins on Activity diagrams
	Modes	UML Collaboration and UML State Machines
	Properties	UML::Comment stereotyped with «AADL_Properties»

<i>AADL properties</i>	<i>Marte Design</i>		<i>Marte Analysis</i>
Compute_execution_time:	NA	NA	"ExecTime: NFPDuration[*]" attribute on <i>SaStep</i> or <i>SaCommStep</i> stereotype
Time_range			"Deadline: NFPDuration[]" attribute on <i>SaStep</i> or <i>SaCommStep</i> stereotype
Compute_Deadline			"MessageQueuePolicyKind" attribute
Queued_Processing_Protocol enumeration			"MessageQueuePolicyKind" attribute
	FIFO		"FIFO" enumeration literal from "QueuePolicyKind" enumerate
	Other		"Other" enumeration literal from "QueuePolicyKind" enumerate

The following example illustrates a "compute_pressure" subprogram owned by a UML class called "library". Subprogram owners modelling feel free to the designer.

```

subprogram compute_pressure
features
raw_data : in parameter;
filtered_data : out parameter;
end compute_pressure;

```

Figure A.9 - Subprogram AADL example

Figure A.10 - Subprogram representation

Access to subprogram components will be detailed in subprogram access section A.2.6.3.

A.2.4 Execution Platform Components

Execution platform component UML profile is illustrated on Figure A.11.

A.2.4.1 Processor

A processor is an abstraction of hardware and associated software that is responsible for scheduling and executing threads. Processors can execute threads that are declared in application software system, or threads that reside in components accessible from those processors.

Component and associated features representation

AADL Concept	UML Profile
--------------	-------------

Processor		«hwProcessor» stereotyped UML Class
Type	Server subprogram	«server_subprogram» stereotyped UML Dependency between server components and the called subprogram (UML Operation)

Propagation_delay			<i>Nfp</i> stereotyped attribute defined by the end-user
Transmission_Time			“ExecTime: NFPDuration[*]” attribute on <i>SaStep</i> or <i>SaCommStep</i> stereotype
Allowed_Message_Size			“MessageSizeElements” attribute on <i>MessageComResource</i> stereotype

A.2.4.4 Device

Device abstractions represent entities that interface with the external environment of an application system. Those devices often have complex behaviours. They may have internal processors, memory, and software that are executed on an external processor. Alternatively, they may require driver softwares that are executed on an external processor. A device's external driver software may be considered as a part of a processor's execution overhead, or it may be treated as an explicitly declared thread with its own execution properties.

Component and associated features representation

AADL Concept		UML Profile
Device		«hwDevice» stereotyped UML Class

Type	Server subprogram	«server_subprogram» stereotyped UML Dependency between server components and the called subprogram (UML Operation)

Figure A.11 - Execution platform components UML representation

A.2.5 System

A.2.5.1 System Composition

The system abstraction represents a composite of software, execution platform, or system components. System abstractions can be organized into a hierarchy that can represent complex systems of systems as well as the integrated software and hardware of a dedicated application system.

Component and associated features representation

AADL Concept		Mapping proposal
System		UML::Class stereotyped «block»

Type	Server subprogram	«server_subprogram» stereotyped UML Dependency between server components and the called subprogram (UML Operation)
	Port	MARTE Flow Ports
	Port group	UML::Class stereotyped with «port_group»
	Requires/Provides bus access	UML Dependency or UML Realization system component and bus associated Interface.
	Require/Provides data access	UML Dependency or UML Realization between the system and the Data associated Interface
	Flows specifications	UML Activity diagram
	Properties	UML::Comment stereotyped with «AADL_Properties»
Implementation	Subcomponents (data, process, processor, memory, bus, device, system)	UML Part of System
	Subprogram calls	None
	Connections	UML Connectors between Ports of the UML Class and Ports of the contained UML Parts.
	Flows	UML Activity diagram
	Modes	UML Collaboration and UML State Machines
	Properties	UML::Comment stereotyped with «AADL_Properties»

A.2.5.2 Binding

For a complete system specification (one that can be instantiated), software components must be bound to appropriate execution platform components. For example, threads must be bound to processing elements and processes must be bound to memory. Similarly, inter processor connections must be bound to buses, and subprogram calls must be bound to their server subprogram. These bindings are defined through property association.

Component and associated features representation

AADL Concept		Mapping proposal
Binding		«allocation» stereotype on UML::Dependency between software and execution platform components.
	Properties	UML::Comment stereotyped «AADL_Properties».
	Binding connection properties	«AADL_Properties» stereotype applied on UML::Comments on the binding feature.

In the following example, the "a_client_process" component is bound to the "a_client_processor" component. Both components are bound by an "allocation" stereotyped UML dependency. An UML Comment is associated to this UML Dependency, containing the binding properties.

```

system implementation a_client.impl
subcomponents
the_processor : processor a_client_processor;
the_process : process a_client_process;
properties
Actual_Processor_Binding => reference the_processor applies to the_process;
end a_client.impl;

```

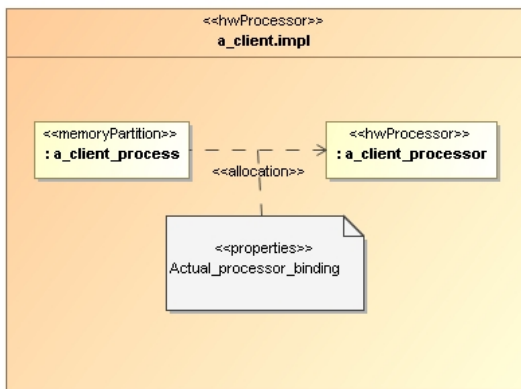

Figure A.12 - System binding representation

A.2.6 Features and shared access

A.2.6.1 Port and Port connections

A port represents a communication interface for the directional exchange of data, events, or both (event data) between components. Connections are linkages representing the communication of data between components through ports of different threads or between threads and processor or device component.

Component and associated features representation

AADL Concept		Mapping proposal
Port		MARTE Interaction Port
Port direction (in, out, in/out)	In, out, in/out port (event data,data, event)	MARTE Interaction Port direction attribute and FlowSpecification or MsgSpecification direction attribute.

Port type	Event port	MARTE MsgPort associated to a FlowSpecification interface
	Data port	MARTE FlowPort associated to a MsgSpecification interface
	Event/Data Port	MARTE MsgPort associated to a FlowSpecification interface and MARTE FlowPort associated to a MsgSpecification interface
Connections	Immediate Connections	UML Connectors between MARTE Interaction ports
	Delayed Connections	'delayed ^a stereotyped UML Connector MARTE Interaction ports
	Properties	'AADL_Properties ^a stereotyped UML Comment

<i>AADL properties</i>	<i>Marte Design</i>	<i>Marte SW/HW platform</i>	<i>Marte Analysis</i>
Compute_execution_time			Time and Deadline are either specified in the associated communication media or component
Compute_Deadline			
Queue_size			"MessageQueueCapacityElements" attribute on <i>MessageComResource</i> stereotype
Queue_Processing_protocol			"Mechanism" attribute on <i>MessageComResource</i> stereotype available values are "MessageQueue, Pipe, BlackBoard, undef, other)
Overflow_handling_protocol			<i>Nfp</i> stereotyped attribute defined by the end-user, typed bt end-user defined enumeration
Dequeued_protocol			<i>Nfp</i> stereotyped attribute defined by the end-user, typed bt end-user defined enumeration

Data flow ports are represented by MARTE FlowPorts (stereotyped "FlowPort") and associated to a "flowSpecification" stereotyped interfaces managing dataTypes sending and receiving out/in of the components. The port isAtomic attribute will be set to "false". The flowSpecification interface direction attribute will specify the flow direction.

Event ports represents ports sending out or receiving signals. They are represented by MARTE MsgPorts (stereotyped "msgPort"). These ports are associated to an interface able to receive/send signals, interfaces stereotyped by the MARTE "SignalSpecification" stereotype. The port isAtomic attribute will be set to "false. The msgSpecification interface direction attribute will specify the flow direction.

EventData ports are represented by both (msgPorts and flowPorts) concepts. So, they will be stereotyped by both stereotypes: "flowPorts" and "msgPort".

Figure A.13 represents in and out data ports of the "read_thread" component. "data_in" and "data_out" are FlowPorts, typed by the "flowSpecification" stereotyped interface data_interface.

```
thread read_data
features
in_data : in data port data1;
out_data : out data port data1;
end read_data;

thread basic_control
features
in_data : in data port data2;
out_data : out data port data2;
end basic_control;

process implementation control_speed.impl

read_data : thread read_data;
control : thread basic_control;
connections
delayed_C1 : data port read_data.out_data ->> control.in_data;
properties
Period => 50ms;
end control_speed.impl;
```

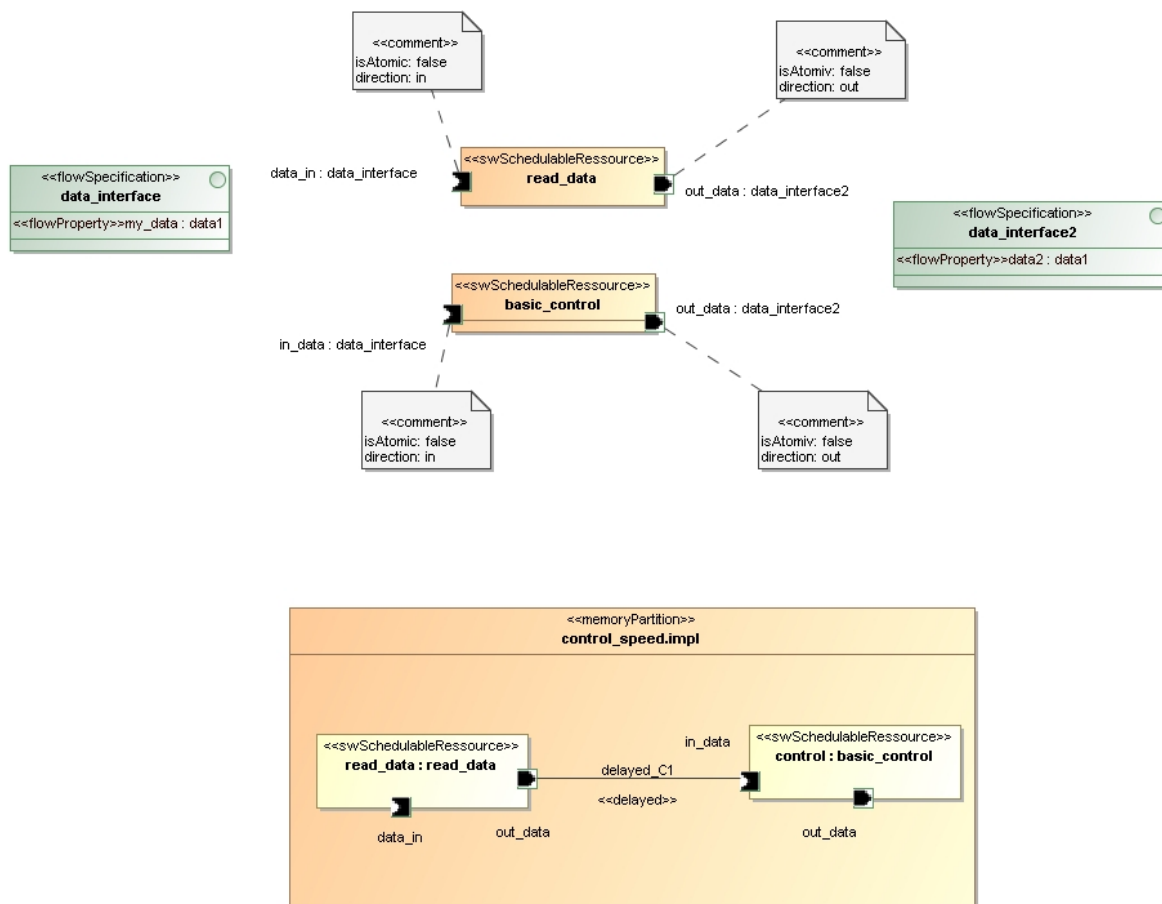

Figure A.13 - Port representation

A.2.6.2 Port Group

The port group abstraction represents a collection of ports or other port groups. Inside the component, ports of a port group can be connected individually; outside the component, the port group is considered as a single connectable entity.

Component and associated features representation

AADL Concept		UML Profile
Port Group		«port_group» stereotyped UML class
Inverse property		«port_group» stereotype attribute

From the component inside, PortGroups are represented as UML Parts connected through UML delegation connectors to the Component Ports represented as a UML Port. From the component inside, the port group can be connected through connectors to component subcomponents.

The portGroup " GPSBasic_socket" can be linked to Satellite_position subcomponents via the Wakeup and Observation ports, and seen as a single port via the Position port.

```

process Satellite_position
features
    Position : port group GPSBasic_socket ;
end Satellite_position ;

port group GPSbasic_socket
features
Wakeup : in event port ;
Observation : out data port GPSLib::position;
end GPSbasic_socket;

```

Figure A.14 - Port group AADL example

Figure A.15 - Port group UML representation

A.2.6.3 Subcomponent Access and data access connections

Components such as buses or data might be accessed by the system through an explicit declaration access in component types. Provides indicates that the component provides access to a data or bus component within it; requires indicates that a component requires access to a data or bus component that is external to it.

Each data or bus will implement an interface providing access to the data/bus service. This feature is represented by a UML Realisation between a component and its provided interface. Each component requiring an access to a bus or data component will use this interface (Uml Dependency) as illustrated in the following example. The required client component will access to the interface via an UML port.

Access connections designate access to shared data components by concurrently executing threads or by subcomponents executing within a thread. They also represent communication between processors, memory, and devices by accessing a shared bus.

```

process control
features
    cc_set_point_data : requires data access data_sets.set_points;
    error_log_data : provides data access log.error_logs;
end control;

A.2.6.4 Subprogram Calls

Subprogram calls (local to threads) are declared through calls declarations within a thread or subprogram implementation. The subprogram that is called must be declared through a subprogram type declaration and possibly a subprogram implementation declaration.

Component and associated features characteristics

AADL Concept	UML Profile
Subprogram	UML Operation within a UML Class
Server Subprogram	«server_subprogram» stereotyped UML Dependency between server components and the called subprogram (UML Operation)
Subprogram call sequence	UML Messages on UML sequence diagrams

Subprogram call sequences are represented as UML messages in UML sequence diagrams as shown in Figure A.21, each subprogram calling its own subprograms like denoted in Figure A.22. Each Subprogram OwnerClassifier instances (adjust.level and find.temp_valuesStaying as library container) is represented trough a lifeline, and subprogram call through messages between them.

In the following example, the two messages (aquire.temps() and adjust.level()) from the control.thermal_control lifeline represents the subprogram call sequence.

```

thread implementation control.thermal_control
calls
{
get_temp: subprogram acquire.temp;
adjust_level: subprogram adjust.level;
};
end control.thermal_control;

subprogram implementation acquire.temp
end acquire.temp;

subprogram implementation adjust.level
calls
{
find_scale_values: subprogram find.temp_values;
};
end adjust.level;

subprogram implementation find.temp_values
end find.temp_values;

```

Figure A.20 - Subprogram call sequence

Figure A.21 - Linear call

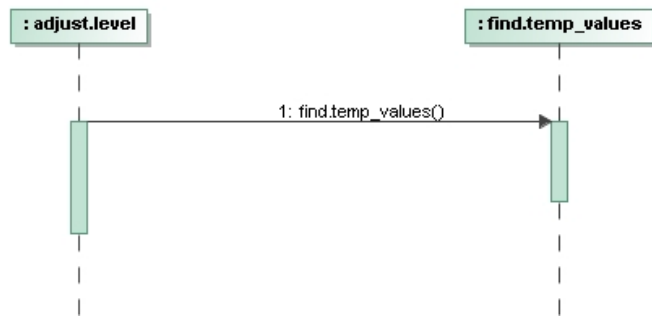

Figure A.22 - Independant subprogram calls

A.2.6.5 Server Subprogram Calls

For subprogram calls called towards other threads, synchronous Remote Calls to a server subprogram are used. The client calls the subprogram, which calls the server subprogram on the remote process as illustrated on the following illustration. These server subprogram call is represented by the "server subprogram" stereotyped UML Dependency between the caller component and the called subprogram. The recording "Actual_Subprogram_Call" property, specifying the binding between the subprogram call to the server subprogram, is modeled as a dependency between the subprogram and server subprogram methods. The Binding properties appear in a UML Comment applied to the Dependency.

AADL Concept	UML Profile

A.2.7 Mode

A modes abstraction is an explicitly defined configuration of contained components, connections, and property value associations. Modes represent alternative operational states of a system or component. Mode transition models dynamic operational behaviour that represents switching between configurations and hanges in components internal characteristics.

Mode and associated features representation

AADL Concept	UML Profile
Modes and modes transitions	UML State machine diagram. Each mode is represented by an UML state, connected by transition representing mode switching. Each triggered events is prefixed by the associated component and port name.
Mode configuration	UML Collaboration represents element connections for a specific mode.
Modes specific sequence calls	UML Sequence diagram

Figure A.28 - AADL mode specific code

A.2.8 Flows

AN AADL flow is logical flow of information through through a sequence of threads, processors, devices and connections. An end-to-end flow represents a complete path through the system, starting at a flow source, ending at a flow sink, passing through components (flow paths) and between components over connections. Flow specification declarations are made within component type declarations, specifying externally visible flows through flow sources, flow sinks and flow paths. Flow implementation specification relies on component implementations, specifying how the flow is realized as a sequence of flows through subcomponents along connections from the flow in port to the flow specification out port. An end-to-end flow represents the logical flow from the source to the destination.

Component and associated features characteristics

AADL Concept	UML Profile
Flow sink	UML InputPin stereotype “flow sink” in an UML Activity Diagram.
Flow source	UML OutputPin stereotype “flow source” in an UML Activity Diagram.
Flow path	UML Object Flow between UML Object Pins in an Activity Diagram.
End-to-end flow	Reference activity diagram connected by Object Flow representing the connections in Activity Diagrams.

Figure A.34 - AADL flow example

A.2.9 Properties

In AADL, Properties provide information about components (type and implementations), subcomponents, features, connections, flows, modes and subprogram calls. Each property is characterized by a name, a type and a value.

All AADL element properties will be grouped together in an UML::Comment stereotyped "AADL_Properties".

Component and associated features characteristics

AADL Concept		UML profile
Property		UML Note stereotype «AADL_Properties» linked to concerned element

A.3 EAST/ADL2.0 models with MARTE

EAST-ADL is an architecture description language, dedicated to automotive embedded electronic systems, developed in the context of the ITEA cooperative project EAST-EEA (<http://www.easteea.net/>) finished in 2004. This language is intended to support the development of automotive embedded software, by capturing all the related engineering information. The scope is the embedded system (hardware and software) and its environment.

The ATESSST project (www.atesst.org) is aimed at refining the EAST-ADL language in the context of dependability concerns, aligning with OMG standards and the new automotive domain standardization AUTOSAR (<http://www.autosar.org/>).

To cover dependable systems, requirement constructs will be enriched to satisfy the needs of different integrity levels and the modeling entities will be refined to support necessary analysis methods, and an engineering process for safety. Transversal to these concepts, with the same consideration for dependability, the variability constructs of EAST-ADL will be improved to support vehicle product lines, the major productivity driver in automotive industry.

The EAST ADL2 abstraction layers are used to allow reasoning of the features on several levels of abstraction. Note, however, that the abstraction levels are only conceptual; the modeling elements are organized according to the artifacts which may span more than one of these layers.

Entities on different abstraction levels are related with a Realization association, where applicable, to allow traceability. Traceability can also be deduced from the requirements structure.

The EAST ADL2 abstraction layers with their corresponding artifacts are:

- Vehicle layer, with the Vehicle Feature Model describing user visible features such as anti-lock braking or windscreen wipers.
- Analysis level with Functional Analysis Architecture capturing the behavior and algorithms of the Vehicle Feature Model functions. There is an n-to-m mapping between Vehicle Feature Model entities and Functional Analysis Architecture entities, i.e., one or several functions may realize one or several features.
- Design level with Functional Design Architecture, representing a decomposition of functionality in the Functional Analysis Architecture. The decomposition has the purpose of making it possible to meet constraints regarding allocation, efficiency, re-use, supplier concerns, etc. Again, there is an n-to-m mapping between entities on Functional Design Architecture and Functional Analysis Architecture. Non-transparent infrastructure functionality of the BasicSWArchitecture, such as mode changes and error handling are also represented on a Design Level.
- Implementation level with the ImplementationArchitecture represented by HardwareArchitecture, BasicSWArchitecture and ApplicationSWArchitecture based on AUTOSAR concepts.
- Operational level, this describes the binary entities and their related tools.
- The Hardware Architecture and Environment Model span several abstraction levels. The Hardware Architecture contains models Electronic Control Units, ECUs, communication links, sensors and actuators and their connections.

The Environment model contains Environment functions which are encapsulations of plant models, i.e. models of the behavior of the vehicle and its non-electronic systems. The environment model is only conceptual and is not an ADL entity.

This part is non-normative and will be completed within the finalization task force. The intend is to describe the usage of MARTE for building EAST-ADL2-like models as done previously for AADL-like models.

Annex B: Value Specification Language (VSL)

(normative)

B.1 Overview

This annex provides detailed definition of the abstract (MOF compliant metamodel) and concrete (textual grammar) syntax for specifying expressions in MARTE. The MARTE expression language is used to specify the values of constraints, properties and stereotype attributes particularly related to non-functional aspects. In fact, this expression language can be used by profile users in tagged values, body of constraints, and in any UML element associated with value specifications.

In addition, the proposed expression language might be used by any other UML-based specification interested on extending the base expression infrastructure provided by UML. As will be seen below, the MARTE expression language is an extension to the "Value specification" and "DataType" concepts provided by UML. For this reason, we call it Value Specification Language (VSL, in short).

VSL deals with the following requirements:

- How to specify parameters/variables, constants, and expressions in textual form.
- How relationships between different parameters/variables, or constant values are to be defined with support on arithmetic, logical, relational, and conditional expressions.
- How different time values and assertions are to be defined in UML.
- How to specify composite values such as collection, interval, and tuple values.

VSL expressions can be used to specify non-functional values, parameters, operations, and dependency between different values in a UML model. UML modelers can use VSL to specify non-functional constraints in their models.

Note: This annex is normative in the UML profile for MARTE.

B.2 Domain View

B.2.1 Overview

This section describes the abstract syntax of VSL. In this abstract syntax a number of concepts (metaclasses) from the UML metamodel are reused. These concepts are shown in the models with a gray fill color. Note that, however, we do not formally "import" them from UML, but re-define them with the same semantics in the MARTE namespace. In the UML representation section, we describe how all these metaclasses are actually mapped to UML.

The abstract syntax is divided into several packages. The overall package structure of VSL is shown in Figure 8.1.

- The DataTypes package describes the concepts that define the datatype extensions to UML. In addition to primitive and enumeration datatypes, it includes further specializations for composite datatypes and subtypes.
- The LiteralValues package includes literal constant values of different primitive types. Besides UML literals, this package distinguishes, among others, Real and DateTime literals

- The Expressions package describes the structure of expressions, including variables and reference values to UML model elements.
- The CompositeValues package defines four kinds of composite values: interval, collection, tuple and choice.
- The TimeExpressions package presents specialized syntax for time value specifications and expressions.

The purpose and contents of each sub packages denoted in Figure B.1 are described in subsequent sections.

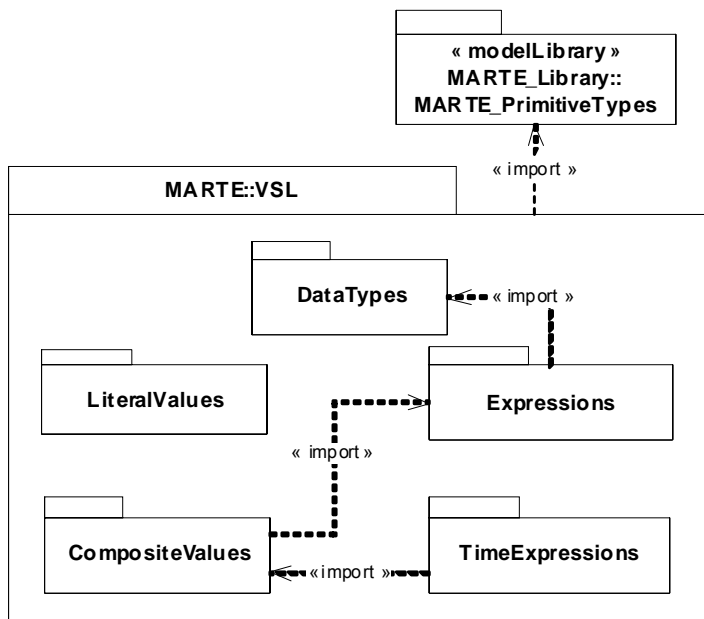

Figure B.1 - Structure of the VSL framework

B.2.2 The Datatypes package

A datatype is a type whose instances are identified only by their value. Instances of a given datatype consist of a set of distinct values, characterized by properties and operations on those values. A value space is the set of values for a datatype. The value space of a given datatype can be defined either by enumeration, axiomatically from fundamental notions, or as a subset of values from some already defined value space.

VSL is a typed language. Each value specification, including expressions, has a type that is either explicitly declared or can be statically derived. Evaluation of an expression yields a value of this type.

The model of datatypes used in this specification is said to be an "abstract computational model". It is "computational" in the sense that it deals with the manipulation of information by computer systems and makes distinctions in the typing of data units which are appropriate to that kind of manipulation. It is "abstract" in the sense that it deals with the perceived properties of the data units themselves, rather than with the properties of their representations in computer systems.

In this specification, datatypes are categorized, for syntactic convenience, into:

- Enumeration types, whose value space is defined by enumeration.
- Primitive types, which are defined axiomatically without reference to other datatypes.

- Subtypes, which are defined in terms of other datatypes.
- Composite types are aggregates of value spaces which can be seen as an organization of specific datatypes.

Figure B.2 - VSL::DataTypes package

Note that the Datatype package preserves the same structure and semantics as in UML, but it extends UML in the following ways:

- Like in UML, DataTypes may contain attributes to support modeling of structured data types. However, dissimilar kinds of structures, with different syntax and semantics, are defined in our language. CompositeType is the metaclass that congregates composite data types. Each kind of composite type (interval, collection, tuple, and choice) has a set of attributes defining particular structures of data types.
- The set of owned operations for a data type comprises those operations on the data type values, possibly yielding values of the owner data type, of the Boolean data type, or, in some cases, of other existing data types. In general, there is no unique collection of operations for a given data type. This specification provides a set of operations for each MARTE data type, which is sufficient for most purpose in this domain. However, this does not limit the capacity of the language to accept new operations in specialized or new data type libraries.
- A Subtype is a data type derived from an existing data type, designated the base data type, by restricting the value space to a subset of that to the base data type whilst maintaining all operations. Particularly, a Bounded Subtype defines a subtype of any ordered data type by placing new minimum and maximum value bounds on the value space.
- Composite types are composed of values which are made up of values of the owned attributes. CollectionType describes a list of elements of a particular given type. TupleType combines different types into a single aggregate type. IntervalType defines a collection of values, having the same type, contained between two given values. ChoiceType generates a data type each of whose values is a single value from any of a set of alternative data types.

Note that composite types involve an indirect way to define data type properties. For instance, the intervalAttribute association end of IntervalType is of type Property. This implies that the multiplicity, uniqueness and order of the bound elements is specified by a data type property (referenced by intervalAttribute), which is defined when a given composite type is created. Thus, for IntervalTypes, the multiplicity of the referenced property must be '[2]' in order to guarantee that the interval value specifications will have two value elements (the max. and the min. values of the interval).

B.2.3 The LiteralValues package

LiteralSpecification is an abstract literal expression that represents a constant. In addition to the existing literal constants supported by UML, this language includes DateTime, Real, and Default literals (Figure B.3). While the first two are actually related to requirements in the MARTE domain, the last one supports a notation for unspecified values that should take a pre-declared default value.

DateTime literal represents an instant in time expressed as a calendar date and/or time format.

Real literal is a constant value expressing a computational approximation to a mathematical real number, without bound values.

EnumerationSpecification is a value specification that identifies an EnumerationLiteral.

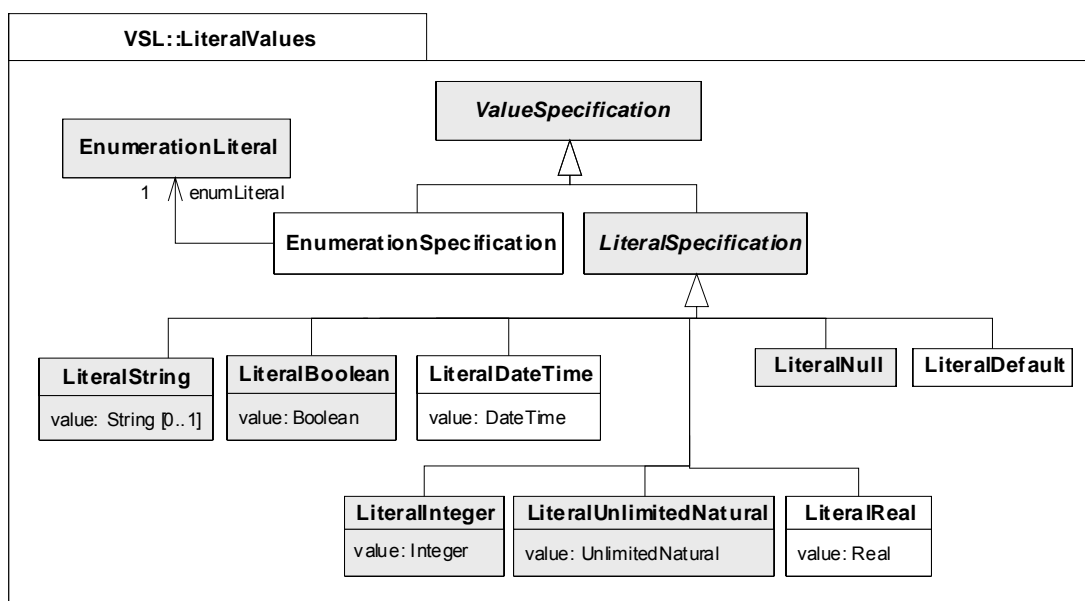

Figure B.3 - Literal Values package

B.2.4 The Expressions package

An expression represents a node in an expression tree. If there are no operands, it represents a terminal node. If there are operands, it represents an operator applied to those operands. In either case there is a symbol associated with the node. The interpretation of this symbol depends on the context of the expression.

Expressions are used to derive values from other values or expressions. An expression can be a simple literal or variable, or it can be a compound expression (arithmetic, logical, or time expressions) formed by combining operands and Operation Call Expressions.

The basic structure in the package consists of Variable Call/Declaration Expression, Property Call Expression, Operation Call Expression, and Conditional Expression (Figure B.4).

Variables are typed elements for passing data in expressions. The variable can be used in expressions where the variable is in scope. A Variable Call Expression is an expression that consists of a reference to a variable. Variable creates a variable with a given name, data type, and nature (input, output, input/output).

Variables are declared in a given Expression Context. The Expression Context's name attribute is used for identification of the variable elements. A Expression Context provides a container for variables. It provides a means for resolving conflicting global variables by allowing Variable Call Expressions of the form `exprContext1::subContext2::varX`. Concrete rules to construct the derived attribute "variable" of Variable Call Expression, are defined in the Section "UML Representation".

A Property Call Expression is used to refer to Properties in the UML metamodel.

An Operation Call Expression refers to an operation defined in a UML Classifier. The expression may contain a list of argument expressions if the operation is defined to have parameters. In this case, the number and types of the arguments must match the parameters.

This metamodel does not define explicitly the context of properties and operations and the namespace that the corresponding call expressions must use. When specifying values making reference to properties and operations of their corresponding data types, the namespace is not taken into account. Further usages of this metamodel may define different namespaces for property and operation.

Conditional Expressions define "if-then-else" statements, which can be used inside an expression. The result of evaluating this expression will be the result of the evaluation of the `ifTrueExpr` if the `conditionExpr` is true. Otherwise, the result will be the result of the `ifFalseExpr`.

An Opaque Expression is an uninterpreted textual statement that denotes a (possibly empty) set of values when evaluated. This allows extending VSL to other specialized expression languages.

Figure B.4 - VSL::Expressions package

B.2.5 The CompositeValues package

In general, a composite value can contain zero, one or more component values. Three kinds of composite value specifications are defined: interval, collection, and tuple (Figure B.5).

Collection Specifications represent a list of elements of a particular given type. Individual elements of collections are item Value Specifications. Note that there is no restriction on the item value type of a collection type. This means in particular that a collection type may be parameterized with other collection types allowing collections to be nested arbitrarily deep. Size, uniqueness and order nature of item values are defined by the defining data type.

Interval Specifications describe ordered sets of value specifications represented by two values: the minimum and the maximum value. Additionally, two attributes define whether these two values belong or not to the referred set (isLowerOpen and isUpperOpen).

Tuple Specifications denote structured values of possibly different types. It contains a name, a type, and a value for each item of the tuple value. There is no restriction on the kind of types that can be used to define item values of tuples. In particular, a Tuple Specification may contain other tuple and collection values.

Choice Specification denotes a value of a choice data type (ChoiceType). It contains the name of one of the attribute members (chosenAlternative), which determines the chosen data type, and a value that conforms to the chosen data type. The derived attribute "chosenAlternative" can be constructed with basis on an explicitly chosen data type. When the chosen data type is undefined in a given choice value specification, the chosen alternative can be deduced from the default alternative attribute of the corresponding choice type.

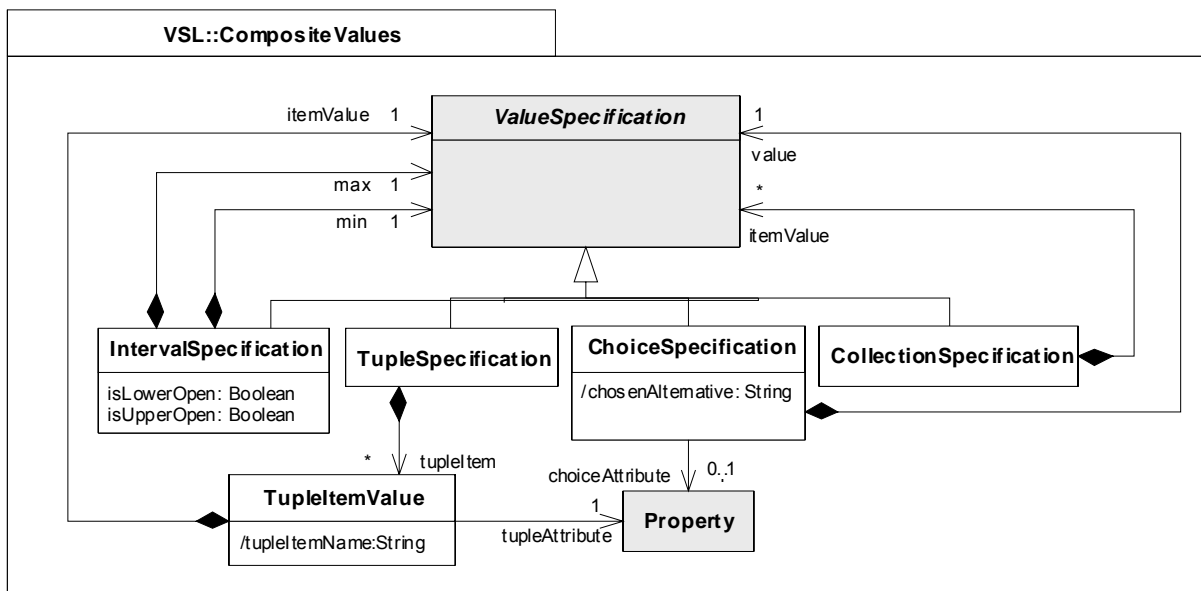

Figure B.5 - VSL::CompositeValues package

B.2.6 The TimeExpression package

This package adds textual capabilities to represent time related expressions. UML has defined a Simple Time model in the Common Behavior package, which already provides means to represent time and durations, as well as a mechanism to refer to event observations with time marks. MARTE extends UML to support more expressive time expressions, constraints, as well as observations in different behavior diagrams. Particularly, VSL's Time Expression model improves UML with the following capabilities:

- One single instant or duration observation can be expressed with an occurrence index. For instance, we can express the "i-th" occurrence of a given event. Whilst the occurrence could be trivial in sequence diagrams (since this diagram is based on occurrence specifications), other diagrams such as state machines and activities may require the explicit identification of the occurrence. In the same way, recurrent interaction fragments represented by a single sequence diagram, such as periodic or loop fragments may require time assertions comparing different instance traces of the sequence diagram. For instance, the duration between the i-th and i+1-th occurrence of an event that triggers a periodic scenario.
- One single instant or duration observation can be expressed with a given condition. For example, the instant time at which a given event occurs (observation) when a specific class' attribute has a value greater than a given constant (condition).
- The jitter of a nominal periodic event or, in general, the jitter between two causal events that occur in instants separated by a nominal time interval. Typical examples are the jitter of a clock event or the maximum jitter introduced by packet networks so that a continuous playout of audio (or video) transmitted over the network can be ensured.

Observation Call Expressions (ObsCallExpression) refers to a single observation (instant and duration observation). It includes an occurrence index expression (occurIndexExpr) that must evaluate to an integer value. Condition expression defines an operational (run-time) condition that completes the definition of a relative event.

The semantics of the occurrence index depends on the observed events. While the absolute order of a given event occurrence regarding another different event could be useful only when both events are synchronized, it exists certain cases where the relative order of an occurrence may be useful to express constraints from different responses of a recurrent scenario. In many systems, each request for service need to be met by a separate response, but the two need not happen at the same time. For instance, let us point to data consistency of FIFO queues as a simple example. Also index "i" enables comparisons between different occurrences of the same event that may not be consecutive (e.g. burstiness).

The condition expression of observation call expression allows having a similar construct as the UML ChangeEvent, which define an expression condition that defines the event occurrence. However, we target to construct textual expressions that not require the explicit definition of a ChangeEvent element.

TimeExpression is an expression that factorizes different kinds of time related expressions, including instants, durations and jitters.

The Time Expression is given by "expr" which may contain usage of the observations (obsExpr) given by ObsCallExpression. In the case where there are no "obsExpr", the "expr" will contain a time constant. In the case where there is no "expr", there shall be a single "obsExpr" that indicates the instant or duration expression value.

InstantExpression is a time expression that denotes a time instant value.

DurationExpression is a time expression that evaluates to a duration value.

JitterExpression is a duration expression that denotes an unwanted variation (delta) in an event occurrence instant that should occur in periodic intervals.

Instant and DurationIntervalSpecifications are special kinds of interval specifications that have time expressions as upper and lower bounds.

Figure B.6 - VSL::TimeExpressions package

Note that the Time Expressions package only introduces the basis to write time related expressions. For example, this model does not account for the relativistic effects that occur in many distributed systems, or the effects resulting from imperfect clocks with finite resolution, overflows, drift, skew, etc. These capabilities, among others, are defined in the MARTE's Time chapter. In the same way, measurement units and other time value qualifiers are defined in the NFP modeling chapter.

B.3 UML Representation

This section describes the UML extensions required to support the concepts defined in the previous domain view. The set of extensions to support VSL with UML is organized according to the extension mechanism used for each part of the metamodel. In particular, note that in VSL not every domain concept will result directly in a UML stereotype or tagged value. This is because some domain concepts are defined to be implemented as a separated metamodel.

For instance, we have chosen to only define stereotypes for concepts that are related to data types definition and variable declaration. The group of domain concepts related to value specifications and expressions yields a separated language, thus providing a new metamodel used in a complementary way to the UML one. Indeed, the latter define an extended grammar for textual notations.

Thus, we first describe the extensions concretized in stereotypes. Then, we define the extensions related to the specification of value expressions. It covers the definition of the concrete syntax of VSL for annotating model elements with extended value specifications.

In Annex D.1, we define a model library of primitive DataTypes and its operations, which is intensively used in MARTE, especially to characterize the supported operations in primitive types.

B.3.1 Profile Diagrams

The Figure 8.5 shows the UML extensions for DataTypes definition. The VSL::DataTypes package (stereotyped as profile) defines how the elements of the domain model extend metaclasses of the UML metamodel. These stereotypes are listed in alphabetical order. The semantic descriptions corresponding to these stereotypes and tagged values are provided in B.3.2.

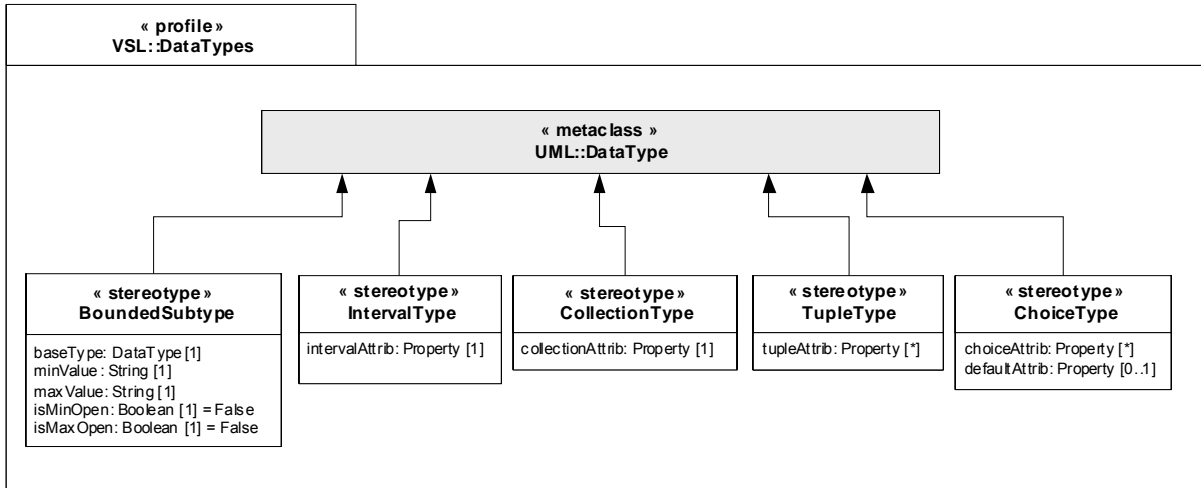

Figure B.7 - UML Extensions for DataTypes definition

Although variables can be created in VSL expressions, we provide the capability to alternatively declare them by means of extended UML Properties. When using UML properties, variable declaration matches to the concept of Parameters in SysML Constraint Blocks.

Figure B.8 shows the UML extensions for Variable definition. The VSL::Variables package (stereotyped as profile) defines how the elements of the domain model extend metaclasses of the UML metamodel. These stereotypes are listed in alphabetical order. The semantic descriptions corresponding to these stereotypes and tagged values are provided in B.3.2.

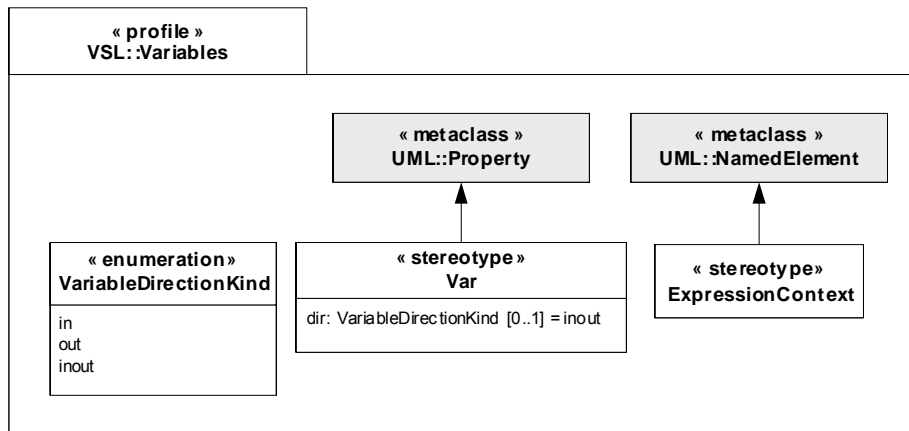

Figure B.8 - UML Extensions for Variable declaration

B.3.2 Profile elements description

B.3.2.1 BoundedSubtype

The BoundedSubtype stereotype maps the BoundedSubtype domain element (section F.13.1) defined on Annex F.

Bounded Subtype is a kind of subtype. A subtype is a data type derived from an existing data type, designated the base data type, by restricting the value space to a subset of that of the base data type whilst maintaining all operations. BoundedType creates a subtype of any ordered datatype by placing upper and/or lower bounds on the value space (minValue and MaxValue).

Extensions

- DataType (from UML::Kernel).

Generalizations

- None.

Associations

- None.

Attributes

- baseType: UML::Classes::Kernel::DataType [1]
designates an ordered datatype.
- minValue: String [1]
defines a string which specifies that the value space is limited to this value in his lower bound.
When minValue is "*", it indicates that no lower bound is being specified.
- maxValue: String [1]
defines a string which specifies that the value space is limited to this value in his upper bound.
When maxValue is "*", it indicates that no upper bound is being specified.
- isMinOpen: Boolean [1]
defines if minValue is excluded in the bounded value space.
- isMaxOpen: Boolean [1]
defines if maxValue is excluded in the bounded value space.

Constraints

- None

B.3.2.2 ChoiceType

This stereotype maps the "ChoiceType" domain element defined on Annex F.

Choice Type generates a data type each of whose values is a single value from any of a set of alternative data types. Choice Type combines different types into a single data type. Instances of choice data types belong to only one of the member types. This type is similar to the C union type and the Ada/Pascal "variant-record". When all the attributes of the extended data type participate as alternatives of the choice type, choiceAttrib can be left undefined.

Extensions

- DataType (from UML::Kernel)

Generalizations

- None

Associations

- None

Attributes

- choiceAttrib: UML::Classes::Kernel::Property [*]
defines the type, size, uniqueness and order of the alternative members of the choice data type. When all the attributes of the extended data type participate as alternatives of the choice type, the choiceAttrib's tagged value can be left undefined.
- defaultAttrib: UML::Classes::Kernel::Property [0..1]
defines the default alternative member of the choice data type.

Constraints

- None

B.3.2.3 CollectionType

This stereotype maps the domain concept "CollectionType" defined on page 557.

Collection Type describes a list of elements of a particular given type. Part of every collection type is the declaration of the type of its elements by means of the CollectionAttribute. I.e., a collection type is parameterized with an element type. Note that there is no restriction on the element type of a collection type. This means in particular that a collection type may be parameterized with other collection types allowing collections to be nested arbitrarily deep.

Extensions

- DataType (from UML::Kernel).

Generalizations

- None

Associations

- None

Attributes

- collectionAttrib: UML::Classes::Kernel::Property [1]
defines the element type, size, uniqueness and order kind of this composite data type.

Constraints

- None

B.3.2.4 IntervalType

This stereotype maps the domain concept "IntervalType".

Interval type is a composite data type defining a set of values by means of two bound limits. The minAttribute defines a single value which will designate the lower bound of the Interval. The maxAttribute defines a single value which defines the upper bound of the Interval.

Extensions

- DataType (from UML::Kernel)

Generalizations

- None

Associations

- None

Attributes

- minAttrib: UML::Classes::Kernel::Property [1]
defines the lower bound part of this composite data type.
- maxAttrib: UML::Classes::Kernel::Property [1]
defines the upper bound part of this composite data type.

Constraints

- None

B.3.2.5 TupleType

This stereotype maps the domain concept "TupleType".

Tuple Type combines different types into a single composite type. The parts of a Tuple Type are described by its attributes, each having a name and a type. There is no restriction on the kind of types that can be used as part of a tuple. In particular, a Tuple Type may contain other tuple types and collection types. Each attribute of a Tuple Type represents a single feature of a TupleType. Each part is uniquely identified by its name. When all the attributes of the extended data type participate in the tuple structure, tupleAttrib can be left undefined.

Extensions

- DataType (from UML::Kernel)

Generalizations

- None

Associations

- None

Attributes

- tupleAttrib: UML::Classes::Kernel::Property [*]
attribute defining the type, size, uniqueness and order kind of the structured elements of this composite data type. When all the attributes of the extended data type participate in the tuple structure, the tupleAttrib's tagged value can be left undefined.

Constraints

- None

B.3.2.6 Var

This stereotype maps the domain concept "Variable".

Variables are typed elements for passing data in expressions. Variable creates a variable with a given name, data type, and nature (input, output, input/output).

Extensions

- Property (from UML::Kernel)

Generalizations

- None

Associations

- None

Attributes

- dir: VariableDirectionKind [0..1]
nature of the created variable: input, output, input/output. The complete semantics of this attribute depends on the context on which the variable is created

Constraints

- None

B.3.2.7 ExpressionContext

This stereotype maps the domain concept "ExpressionContext".

Variables are declared in a given Expression Context. The Expression Context's name attribute is used for identification of the variable elements. A Expression Context provides a container for variables. It provides a means for resolving conflicting global variables by allowing Variable Call Expressions of the form ExprContext1::SubContext2::varX.

Extensions

- NamedElement (from UML::Kernel)

Generalizations

- None

Associations

- None

Attributes

- None

Constraints

- None

B.3.3 Concrete syntax of value specification

This section defines VSL for specifying value specifications. We base the syntax and semantics of this textual language on the metamodel (abstract syntax) defined in Sections B.2.3 to B.2.6.

Value Specifications are used to specify the textual value parts of UML models. The value specification could be a simple literal, such as a number, or it could be a complex expression that involves variables and operations. Whatever the expression, the desired value is produced when the expression is evaluated.

The use of expressions and variables clearly presumes that there is a pre-processor that evaluates the values before a model can be analyzed. It also requires a mechanism for supplying the values of independent variables, since this language itself does not have an assignment operation. However, these additional mechanisms are necessary for any system that allows values to be expressed through variables and are not a consequence of using VSL.

Thus, a value in VSL can be specified as a literal value (LiteralSpecification), as a composite value (IntervalSpecification, CollectionSpecification, TupleSpecification), as an expression (Expression), or as a time value or expression (TimeValueSpecification, TimeExpression). The top-level production is defined by:

```
<value-specification> ::= <literal> | <enum-specification> | <interval> |  
                        <collection> | <tuple> | <choice> | <expression> |  
                        <time-expression> | <obs-call-expression>
```

The following are typical examples of the notation for value specification:

Table B.1 - Examples of Value Specifications

NFP Value Specification	Examples of expressions for NFP values
<i>Real Number</i>	1.2E-3 //scientific notation 1234.56 //conventional notation
<i>Variable</i>	In\$timeout //an input variable declaration timeout+(2, us) //an expression calling a variable
<i>Collection</i>	{1, 2, 88, 5, 2} //sequence, bag, ordered set.. {{1,2,3}, {3,2}} //collection of collections
<i>Tuple</i>	(value=2, unit=ms, clock=ck1) //a duration tuple value (2, -, ms, ck1) //a duration tuple value without names.

Table B.1 - Examples of Value Specifications

<i>Interval</i>	[1..251] //interval between integers [A1..A2] //interval between variables
<i>DateTime</i>	06/01/02 12:00:00 //a given calendar time instant
<i>Duration</i>	(endEvent - startEvent) //between two observed events
<i>Operations on values</i>	deadline < timeout + 5.0 //timing constraint
<i>Conditional Expression</i>	V1 == ((clients<6) ? (exp(6)) : 1)

In the following sub-sections, we describe the notation supported for the symbol of values.

B.3.3.1 Literals

Numbers are represented in decimal, binary and hexadecimal form only. Integer, unlimited natural and real numbers are allowed, as are positive and negative numbers. No whitespaces or commas are allowed within numbers. Real numbers may be expressed using the scientific notation.

```
<number-literal> ::= <integer-literal> | <unlimited-natural> | <real-literal>
```

```
<integer-literal> ::= ['+' | '-'] ( <decimal-string> | <hexadecimal-string> | <binary-string> )
```

```
<unlimited-natural> ::= <unlimited-string>
```

```
<real-literal> ::= ['+' | '-'] ( <real-string> | <scientific-real> )
```

```
<scientific-real> ::= <real-string> 'E' ['+' | '-'] <decimal-string>
```

```
<real-string> ::= <decimal-string> ['.' <decimal-string>]
```

```
<hexadecimal-string> ::= '0x' ( ('0'..'9') | ('A'..'F') | ('a'..'f') )+
```

```
<binary-string> ::= '0b' ( '0' | '1' )+
```

```
<decimal-string> ::= ('0'..'9')+
```

```
<unlimited-string> ::= ( ('0'..'9')+ | '*' )
```

The following are typical examples:

```
12345      #positive integer
-123      #negative integer
0xFF      #hexadecimal integer
0b00100111 #binary integer
1234.56   #positive real
1.2E3     #real with scientific notation
*         #infinite value
```

B.3.3.2 Enumeration Specification

An enumeration specification identifies a UML enumeration literal. The notation is simply the name of the enumeration literal.

```
<enum-specification> ::= <enum-id>
```

```
<enum-id> ::= <body-text>
```

For instance,

```
EDF          #a reference to an enumeration literal named 'EDF'
```

B.3.3.3.Boolean Literal

We express Boolean values through two predefined literals: true and false.

```
<boolean-literal> ::= 'true' | 'false'
```

For example:

```
isPeriodic = true
```

B.3.3.3 String Literal

Strings are specified by bracketing a stream of printable characters between single quotes ('). Any printable character can be included in a string. To include the single quote character itself, the two-character combination of backslash and quote (\') is used, while a backslash character can be inserted into a string constant using a double backslash combination (\\). There are no predefined upper limits on the size of strings.

```
<string-literal> ::= ''' ( <body-text> | '\\'' | '\\\\' )* '''
```

```
<body-text> ::= (terminal symbol consisting of string of characters defined in one character set encoding)
```

The following are typical examples:

```
'A simple string'
```

```
'A string with a quote literal (\') included within.'
```

```
'The backslash-quote combination (\\') appearing literally in a string'
```

B.3.3.4 DateTime Literal

DateTime is a special value expressed described by the following extended BNF:

```
<datetime-literal> ::= ( <time-string> [<day-string>] ) | ( <date-string> [<day-string>] ) | ( <time-string> <date-string> [<day-string>] ) | ( <day-string> )
```

```
<time-string> ::= <hr> [':' <min> [':' <sec> [':' <centisec>] ] ]
```

```
<hr> ::= '00'..'23'
```

```
<min> ::= '00'..'59'
```

```
<sec> ::= '00'..'59'
```

```

<centisec> ::= '00'..'99'
<date-string> ::= <year> '/' <mon> '/' <day-of-mon>
<year> ::= '0000'..'9999'
<mon> ::= '01'..'12'
<day-of-mon> ::= '01'..'31'
<day-string> ::= 'Mon' | 'Tue' | 'Wed' | 'Thr' | 'Fri' | 'Sat' | 'Sun'

```

The following are typical examples:

```

12:24:00           #a simple standard time value
12:24:00 2006/02/07 #a simple datetime value
2006/02/07 Tue     #a date value

```

B.3.3.5 Null Literal

A Null Literal allows specifying an undefined value. We use the text "null" to specify a null literal.

```

<null-literal> ::= 'null'

```

B.3.3.6 Default Literal

A Default Literal allows specifying a default value. If a default value exists, it is assigned to the value, otherwise the value remains as a Null value. We use the symbol "-" to specify a default value literal.

```

<default-literal> ::= '-'

```

B.3.3.7 Intervals

Values can be specified as intervals (ranges) of values. The min value and the max value of an interval as to be conform to the same data type. The "interval" value returns all the values counting by one from the initial value to the end value. An interval value can specify if it includes or not the initial and end values. For example, [x..y] stands for left and right closed interval or]x .. x[stands for left and right open interval.

```

<interval> ::= ('[' | ']') <interval-bound> '..' <interval-bound> ('[' | ']')
<interval-bound> ::= <literal-interval-bound> | <tuple-interval-bound> | <choice-interval-bound> | <expression-interval-bound>
<literal-interval-bound> ::= <number-literal> | <datetime-literal>
<tuple-interval-bound> ::= <tuple>
<choice-interval-bound> ::= <choice>
<expression-interval-bound> ::= <expression>

```

The following are typical examples:

```

[1..2]           #a simple numerical interval

```

```
[start..end[ #a variable interval which does not include the value assigned to
the variable "end".
```

B.3.3.8 Collections

It is possible to combine value specifications into a collection of items between a set of parentheses with individual item values separated by commas. There are no predefined limits on the size of collections.

```
<collection> ::= '{' <value-specification> (',' <value-specification> )* '}'
[ '[' <unlimited-natural> ']' ]
```

The following are typical examples:

```
{1, 2, 5, 88} #a simple numerical collection
{'apple', 'orange', 'strawberry'}#a string collection
{1, 3, 45, 2, 3} #a sequence collection
{{1,2,3}, {3,2}} #a collection of collections
```

B.3.3.9 Tuples

Tuple specification enables to describe values that are conformed to tuple data types. The elements of a tuple are named tuple items and consist of a pair of item name and its associated value separated by an equal symbol.

```
<tuple> ::= '(' [<item-name> '='] <value-specification> (',' [<item-name> '=']
<value-specification> )* ')'
<item-name> ::= <body-text>
```

The following are typical examples:

```
(maxValue=10, meanValue=3, minValue=1) #a tuple value specifying three measured
magnitudes
(10, 30, 5) #the same tuple value without itemNames
(10, -, 5) #a tuple value with an Undefined value
```

B.3.3.10 Choice values

Choice value specification denotes a value of a choice data type. It contains the name of one of the attribute members (chosen alternative), which determines the chosen data type, and a value that conforms to the chosen data type. When the chosen alternative name is undefined in a given choice value specification, the chosen alternative can be deduced from the default alternative attribute of the corresponding choice type. In order to avoid double parentheses in value specifications, choice parentheses are optional when the enclosed value is a tuple.

```
<choice> ::= ( [<chosen-alternative-name>] '(' <value-specification> ')' ) | (
[<chosen-alternative-name>] <tuple>)
<chosen-alternative-name> ::= <body-text>
```

The following are typical examples:

```
periodic(period=10, jitter=0.1) #a choice value specifying a chosen alternative
                                "periodic" whose data type is a tuple with two
                                items "period" and "jitter".
```

B.3.3.11 Expressions

An expression can be a simple constant or variable, or it can be a compound expression formed by combining expressions through operator calls. The latter provides a relatively sophisticated capability to express values that are related to each other in possibly very complex ways.

```
<expression> ::= <variable-call-expr> | <variable-declaration> | <property-call-expr> | <operation-call-expr> | <conditional-expr>
```

For instance, the following somewhat contrived example shows a complex case where the tuple value of a timeout tag (expression plus measurement unit) will depend exponentially on the number of clients configured in the system (clients), unless that number is greater than 6, in which case a single maximum value is used:

```
timeout = (abs((clients<6)?(0.5*exp(clients)):(0.5*exp(6))), ms)
```

B.3.3.12 Variables

There are two expressions of variables: call and declaration. A variable call expression is just a name that refers to a variable. Variable declaration creates a variable. In variable declarations, the type and init expression are optional. When these are required, this is defined in the production rule where the variable declaration is used. When the type is not defined, the type "String" is assumed. Variable declarations begin with the "\$" symbol as the first character.

Variables are declared in a given Expression Context (see the UML Profile for Variables in Section B.3.1) The Expression Context's name attribute is used for identification of the variable elements. A Expression Context provides a container for variables. It provides a means for resolving conflicting global variables by allowing Variable Call Expressions of the form `exprContext1::subContext2::varX`. All variable names have a namespace which is defined by the closer UML element stereotyped "ExpressionContext" in which the variables are contained. If no namespace is specified, either the context of the expression is the same as the context of the variable declaration, or there is not exists an ExpressionContext. In the latter case, variables are global to the UML model in which they appear.

```
<variable-call-expr> ::= <variable-name>
```

```
<variable-declaration> ::= [<variable-direction>] '$' <variable-name> [<type-name>] ['=' <init-expression>]
```

```
<variable-direction> ::= 'in' | 'out' | 'inout'
```

```
<variable-name> ::= [<namespace> '.'] <body-text>
```

```
<namespace> ::= <body-text>
```

```
<type-name> ::= <body-text>
```

```
<init-expression> ::= <value-specification>
```

For example:

```
(clock_rate, us)           #a tuple value specifying a variable and a unit
in$timeStamp:DateTime     #a declaration of an input variable for a DateTime
value
```

RMAanalysis.isSchedulable #a property call expression which uses the UML element called "RMAanalysis" as context for a property called "isSchedulable".

B.3.3.13 Property Call Expression

This rule represents property call expressions for an implicit (without namespace) or explicit (with namespace) scoped UML Property metaclass instance.

This metamodel does not define explicitly the context of properties and operations and the namespace that the corresponding call expressions must use. When specifying values making reference to properties and operations of their corresponding data types, the namespace is not taken into account. Further usages of this metamodel may define different namespaces for property and operation.

```
<property-call-expr> ::= <property-name>
<property-name> ::= [<namespace> '.'] <body-text>
<namespace> ::= <body-text>
```

For example:

MyPackage.MyTask.priority #a property call expression which makes reference to the UML property called "priority" defined in the Class "MyTask" which in turn is contained in a Package "MyPackage".

B.3.3.14 Operation Call Expressions

Operation calls are particularly used in the MARTE context to call operations of data type values. An operation call expression has two different forms: normal and infix notations. Some operators (e.g., '+', '-', '*', '/', '<', '>', '<>', '<=' '>=') are used as infix operators. If a type defines one of those operators with the correct signature, they will be used as infix operators. The expression:

a + b

is conceptually equal to the expression:

a.(+)(b)

that is, invoking the "+" operation on a with b as the parameter to the operation.

The infix operators defined for a type must have exactly one parameter. For the infix operators '<', '>', '<=', '>=', '<>', 'and', 'or', and 'xor' the return type must be Boolean.

```
<operation-call-expr> ::= (<value-specification> '.' <operation-name> ['('
<argument-value> [',' <argument-value>]* ')'])
| (<argument-value>
<operation-name> <argument-value>)
<argument-value> ::= <value-specification>
<operation-name> ::= <body-text>
```

B.3.3.15 Conditional Expressions

This expression works like an if-then-else statement.

```
<conditional-expression> ::= <condition-expr> '?' <if-true-expr> ':' <if-false-expr>
```

```
<condition-expr> ::= '(' <variable-declaration> | <variable-call-expr> | <property-call-expr> | <operation-call-expr> ')'
```

```
<if-true-expression> ::= <value-specification>
```

```
<if-false-expression> ::= <value-specification>
```

The result of evaluating this expression will be the result of the evaluation of the <if-true-expr> if the <condition-expr> is true. Otherwise, the result will be the result of the <if-false-expr>.

The following are typical examples:

(clock_rate>5)?(5):(clock_rate) returns either the value 5 if the clock_rate value is greater than 5 or the value of variable denoted by clock_rate.

The conditional operator has a precedence that is below the relational operators, but above the Boolean operators.

B.3.3.16 Time Expressions

A time expression can be a simple constant or variable representing a time value or it can be a compound expression formed by combining observation call expressions. The latter provides a relatively sophisticated capability to specify time expressions that are related to specific events or event occurrences declared in UML models. Observation declarations are defined in the UML model space conforming to the Simple Time model of the Common Behavior package (UML Superstructure).

```
<time-expression> ::= <duration-expr> | <instant-expr> | <jitter-expr>
```

```
<instant-expr> ::= ( ( <datetime-literal> | <variable-call-expr> ) ['+' <duration-expr>] ) | ( <instant-obs-expr> [ '+' <duration-expr> ] )
```

```
<duration-expr> ::= ( <real-literal> | <variable-call-expr> ) | <duration-obs-expr> | ( '(' <instant-obs-expr> '-' <instant-obs-expr> ')' )
```

```
<jitter-expr> ::= ( 'jitter(' <instant-obs-expr> ')' ) | ( 'jitter(' <instant-obs-expr> ',' <instant-obs-expr> ')' )
```

```
<instant-interval> ::= ('[' | ']') <instant-expr> '..' <instant-expr> ('[' | ']')
```

```
<duration-interval> ::= ('[' | ']') <duration-expr> '..' <duration-expr> ('[' | ']')
```

```
<obs-call-expression> ::= <instant-obs-expr> | <duration-obs-expr>
```

```
<instant-obs-expr> ::= <instant-obs-name> [ '[' <occur-index-expr> ']' ] [ ' when ' <condition-expr> ']' ]
```

```
<duration-obs-expr> ::= <duration-obs-name> [ '[' <occur-index-expr> ']' ] [ ' when ' <condition-expr> ']' ]
```

```
<instant-obs-name> ::= [<namespace> '.'] <body-text>
```

<duration-obs-name> ::= [<namespace> '.'] <body-text>

<namespace> ::= <body-text>

<occur-index-expr> ::= <value-specification>

<condition-expr> ::= <value-specification>

Some typical examples of observation-based time expressions are:

t1 #returns the instant time of an event observation "t1" declared in a UML model element "time observation".

d1 #returns the duration time of an action, message or whatever behavior execution observation "d1" declared in a UML model element "duration observation".

t1[i] #returns the instant time of an event observation "t1" declared in a UML model element "time observation". The index "i" is a modifier that indicates that the instant time refers to whatever of the occurrences of the observed event. It is a modifier in the sense that if the observed event is an instance (event occurrence) the expression refers to its type (event).

(t2-t1) #returns the duration between two observed events which their occurrence instants are labeled by "t1" and "t2" and where "t1" occurs before than "t2"

(t1[i+1]-t1[i]) #returns the duration between any two successive occurrences of an observed event whose occurrence instants are labeled by "t1".

t1+d1 #returns the instant time which is defined "d1" units of time after "t1", where "d1" is the duration of an observed action, message or other behavior execution and "t1" is the time at which occurs an observed event.

jitter(t1) #returns the occurrence deviation of an specific event, which is defined by a time observation "t1", regarding its nominal occurrence period. The jitter notation is a modifier in the sense that the referred event is nominally periodic and, additionally, is the observed event is an instance (event occurrence) the expression refers to its type (event).

jitter(t1,t2) #returns the jitter of an specific event which is defined by a time observation "t1". The jitter notation is a modifier in the sense that the referred event is nominally periodic and, additionally, whether the observed event is an instance (event occurrence) the expression refers to its type (event).

B.3.4 Examples

In order to illustrate the extensions proposed by VSL, we present a short example of declaration of extended data types and a set of associated value specifications.

In Figure B.9, we define a representative collection of data types.

From an implementation perspective, VSL data type extensions involve an indirect mechanism to define data type features. For instance, the collectionAttrib tag definition of CollectionType is of type Property (UML Property metaclass). This implies that the size, uniqueness and order of collection elements is specified by a data type property (referenced by collectionAttrib), which is created when the stereotype is applied.

For instance, the Long bounded subtype defines an Integer type whose value space is restricted to the set of integers from -480000 to + 480000.

The IntegerInterval data type defines a data type which composite values are expressed as a pair of integers denoting the set of integers comprised between them.

IntegerVector and IntegerMatrix declare integer value spaces of collections and collection of collections.

Power data type defines a tuple to express an aggregated value containing a value, an expression, a measurement unit and a source. Note that we do not define the tupleAttrib's tagged values. Indeed, this tagged value is optional when all the data type properties participate in the tuple structure (see definition of the TupleType stereotype). This kind of tuple is used in the NFP modeling chapter to declare qualified values.

Arrival pattern type defines a choice type. Two alternative attributes are defined: periodic and sporadic. Each attribute is typed by a tuple type containing the parameters of the alternative choice. Note that we do not define the choiceAttrib's tagged values. Indeed, this tagged value is optional when all the data type attributes are alternatives of the choice type. This kind of type is used to define parameterized values.

Finally, we show a template of Array data type which is used to create arrays of different item type and elements number.

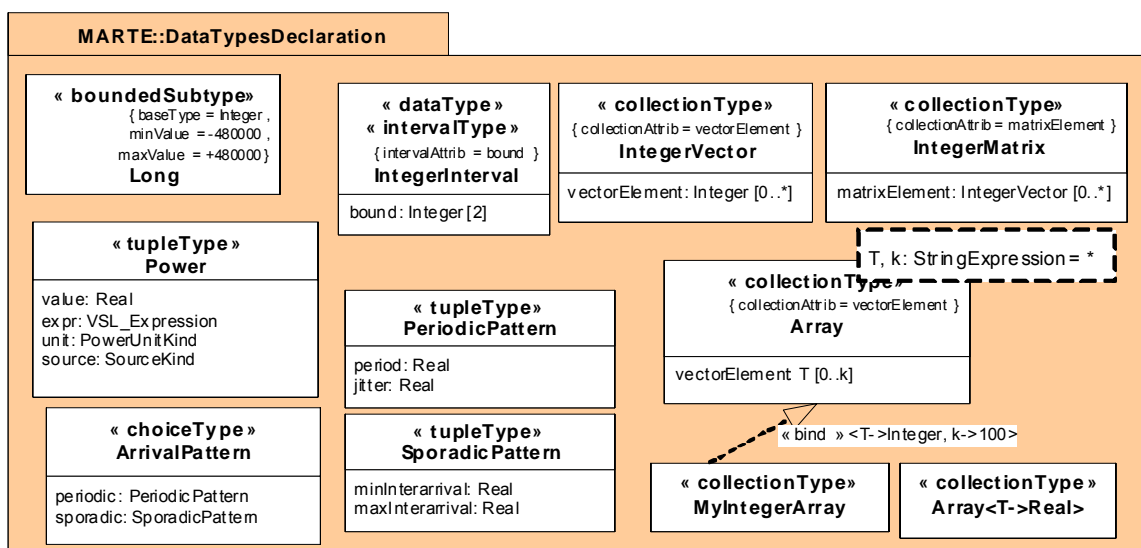

Figure B.9 - Examples of declarations using the UML stereotypes for Datatypes

In Figure B.10, we use these data types to declare a set of contrived properties and their values with the VSL textual syntax.

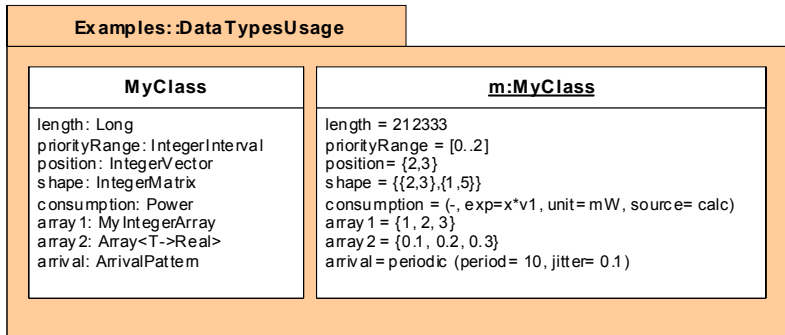

Figure B.10 - Using of the Datatypes created in the example of the previous figure

In order to illustrate the use of time expressions, Figure depicts a sequence diagram with timing annotations and constraints. Note that for completeness of the example, time constraints have been extended in the MARTE's Time modelling chapter. We focus here in the textual language for expressions.

This sequence diagram shows a periodic gate called "start". "Constraint1" in the Interaction "DataAcquisition" determines the period of the gate (100 milliseconds). Additionally, a jitter constraint is attached to the gate, confining its deviation (regarding to the period) to a value shorter than 5 milliseconds. Note that we use the tuple notation to write the magnitude and the measurement unit of duration values. The MARTE's NFP chapter defines the Duration tuple type which allows to assign this measurement unit to a duration value.

After receiving "start", Controller sends a message "acquire" to ask "Sensor" for new data. The duration of the message transmission is constrained to 1 millisecond.

After receiving the acquire message, Sensor must send a message "ack", which must be received by Controller in a maximum of 8 milliseconds after acquire has been sent. In the same way, a "sendData" message is transmitted to Controller in a maximum of 10 milliseconds. "Constraint2" confines the time instant at which the sendData message is received by Controller to 30 milliseconds after Sensor receives the acquire message, if and only if the data value is greater than 5.0.

We suppose here a global clock for all the time annotations. The MARTE's Time modelling chapter introduces further notions to specify global and local reference clocks.

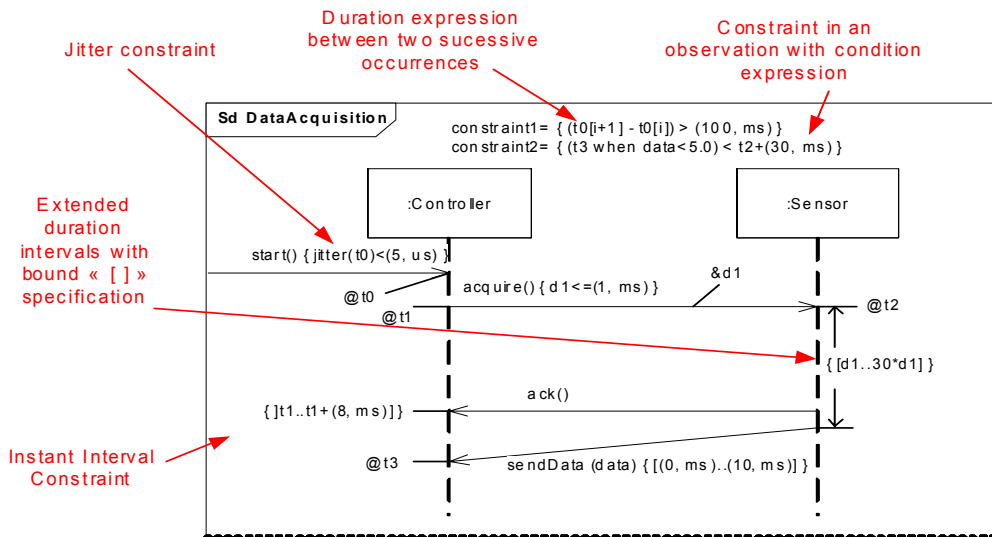

Figure B.11 - Time Expressions and Constraints in Sequence Diagrams with VSL

Annex C: Clock Handling Facilities

C.1 Overview

This annex provides the abstract syntax for specifying clocked values and clock dependencies. Concrete syntax is also proposed: the Clocked Value Specification Language (CVSL) and the Clock Constraint Specification Language (CCSL). These languages reuse the Value Specification Language (VSL) for general expressions on Boolean, Integer, Real...

C.2 Clocked Value Specification

C.2.1 Domain view

A ClockedValueSpecification (CVS) is the specification of a set of instances of time values making reference to Clocks. Since the concept of time covers the two concepts of instant and duration, the CVS domain view (Figure C.17.28) reflects this dichotomy. A ClockedValueSpecification may reference an instance (InstantInstanceValue or DurationInstanceValue) or may be an expression denoting an instance or instances when evaluated. The CVS expressions involve only instants (InstantExpression), only durations (DurationExpression) or both (Span and Translation) in order to combine instants and durations in restricted ways. Interval specifications (InstantIntervalSpecification and DurationIntervalSpecification) are used to specify range of values or uncertainties.

In Figure C.17.28, InstantValueSpecification and DurationValueSpecification are duplicated to improve legibility.

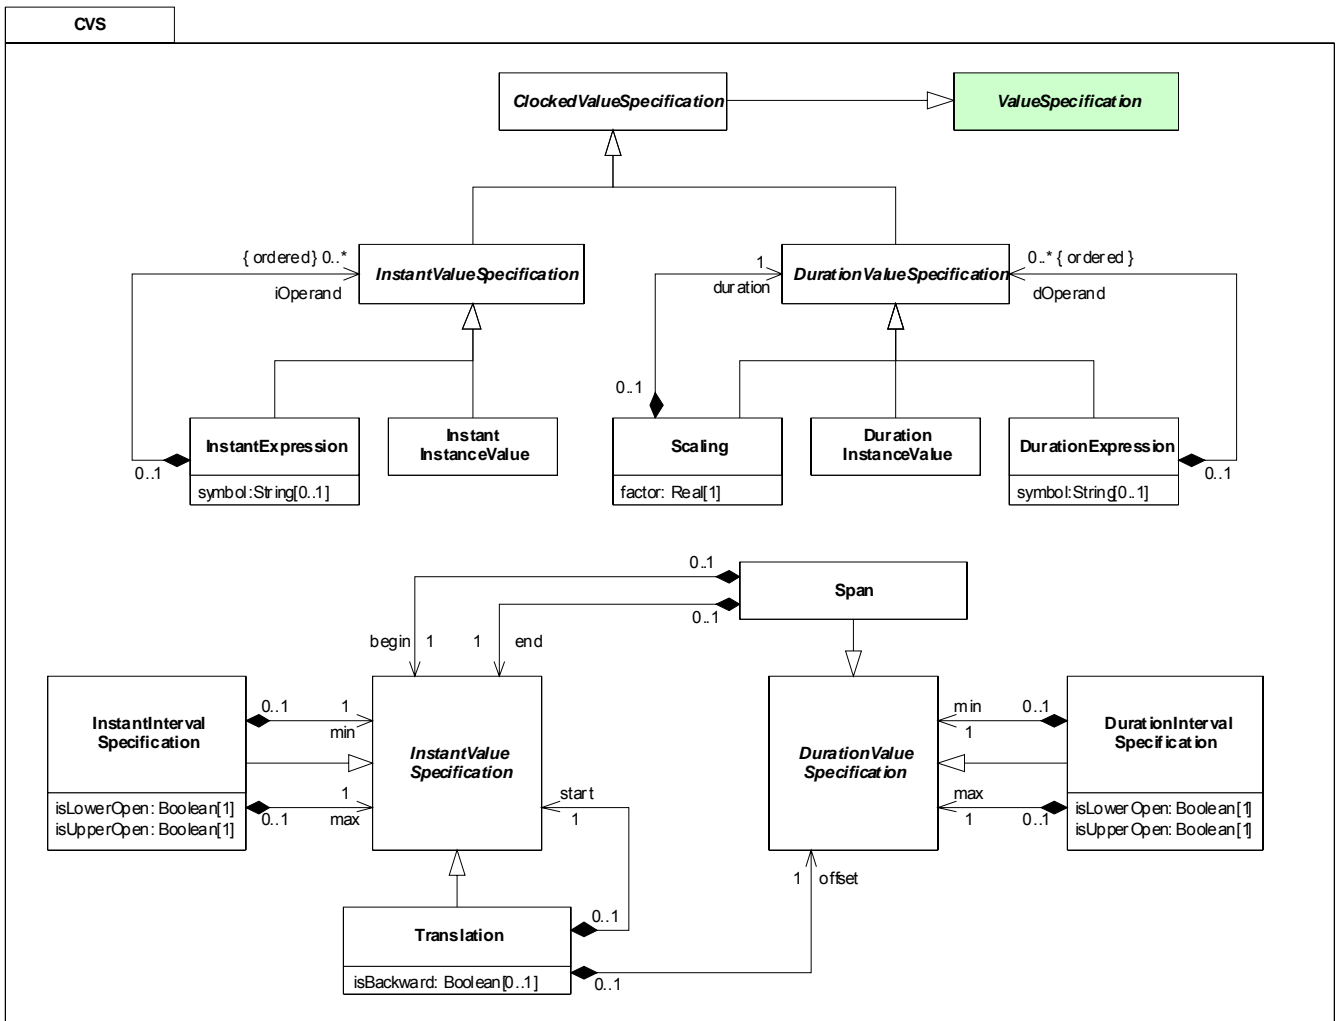

Figure C.1 - CVS domain view

C.2.1.1 ClockedValueSpecification

A ClockedValueSpecification may reference an instance (InstantInstanceValue or DurationInstanceValue) or may be an expression denoting an instance or instances when evaluated.

Generalizations

- ValueSpecification (from UML::Classes::Kernel)

Associations

- None

Attributes

- None

Semantics

A ClockedValueSpecification yields zero or more time values bound to Clocks. A ClockedValueSpecification may reference an instance (InstantInstanceValue or DurationInstanceValue) or may be an expression denoting an instance or instances when evaluated. This is an abstract class.

C.2.1.2 DurationExpression

A DurationExpression is a structured tree of symbols that denotes a set of duration values when evaluated in a context.

Generalizations

- DurationValueSpecification (from CVS)

Associations

- dOperand: DurationValueSpecification[0..*]
specifies a sequence of operands, which are DurationValueSpecifications.

Attributes

- symbol: String[0..1]
the symbol associated with the node in the expression tree.

Semantics

A DurationExpression represents a node in an expression tree. If there are no operands, it represents a terminal node. If there are operands, it represents an operator applied to those operands. In either case there is a symbol associated with the node. The interpretation of this symbol depends on the context of the expression.

C.2.1.3 DurationInstanceValue

A DurationInstanceValue is value that identifies a duration on a Clock.

Generalizations

- DurationValueSpecification (from CVS)

Associations

- None

Attributes

- None

Semantics

A DurationInstanceValue is value that identifies a duration on a Clock.

C.2.1.4 DurationIntervalSpecification

A DurationIntervalSpecification specifies an ordered set of duration value specifications.

Generalizations

- DurationValueSpecification (from CVS)

Associations

- max: DurationValueSpecification [1] specifies the upper bound of the interval.
- min: DurationValueSpecification [1] specifies the lower bound of the interval.

Attributes

- isLowerOpen: Boolean [1] = false
specifies whether the lower bound is in the interval (isLowerOpen set to false) or not (isLowerOpen set to true).
- isUpperOpen: Boolean [1] = false
specifies whether the upper bound is in the interval (isUpperOpen set to false) or not (isUpperOpen set to true).

Semantics

A DurationIntervalSpecification specifies an ordered set of duration value specifications.

C.2.1.5 DurationValueSpecification

A DurationValueSpecification may reference an instance (DurationInstanceValue) or may be an expression denoting an instance or instances of durations when evaluated.

Generalizations

- ClockedValueSpecification (from CVS)

Associations

- None

Attributes

- None

Semantics

A DurationValueSpecification yields zero or more duration values bound to Clocks. A DurationValueSpecification may reference an instance (DurationInstanceValue) or may be an expression denoting an instance or instances of durations when evaluated. This is an abstract class.

C.2.1.6 InstantValueSpecification

An InstantValueSpecification may reference an instance (InstantInstanceValue) or may be an expression denoting an instance or instances of instants when evaluated.

Generalizations

- ClockedValueSpecification (from CVS).

Associations

- None

Attributes

- None

Semantics

An `InstantValueSpecification` yields zero or more instant values bound to `Clocks`. An `InstantValueSpecification` may reference an instance (`InstantInstanceValue`) or may be an expression denoting an instance or instances of instants when evaluated. This is an abstract class.

C.2.1.7 `InstantExpression`

An `InstantExpression` is a structured tree of symbols that denotes a set of instant values when evaluated in a context.

Generalizations

- `InstantValueSpecification` (from CVS)

Associations

- `iOperand: InstantValueSpecification [0..*]`
specifies a sequence of operands, which are `InstantValueSpecifications`.

Attributes

- `symbol: String [0..1]`
the symbol associated with the node in the expression tree.

Semantics

An `InstantExpression` represents a node in an expression tree. If there are no operands, it represents a terminal node. If there are operands, it represents an operator applied to those operands. In either case there is a symbol associated with the node. The interpretation of this symbol depends on the context of the expression.

C.2.1.8 `InstantInstanceValue`

An `InstantInstanceValue` is value that identifies an instant on a `Clock`.

Generalizations

- `InstantValueSpecification` (from CVS).

Associations

- None

Attributes

- None

Semantics

An InstantInstanceValue is value that identifies an instant on a Clock.

C.2.1.9 InstantIntervalSpecification

An InstantIntervalSpecification specifies an ordered set of instant value specifications.

Generalizations

- InstantValueSpecification (from CVS).

Associations

- max: InstantValueSpecification [1] specifies the upper bound of the interval.
- min: InstantValueSpecification [1] specifies the lower bound of the interval.

Attributes

- isLowerOpen: Boolean [1] = false
specifies whether the lower bound is in the interval (isLowerOpen set to false) or not (isLowerOpen set to true).
- isUpperOpen: Boolean [1] = false
specifies whether the upper bound is in the interval (isUpperOpen set to false) or not (isUpperOpen set to true).

Semantics

An InstantIntervalSpecification specifies an ordered set of instant value specifications.

C.2.1.10 Scaling

A Scaling is a special expression that denotes duration values obtained from a DurationValueSpecification by applying a multiplicative factor.

Generalizations

- DurationValueSpecification (from CVS)

Associations

- duration: DurationValueSpecification [1] specifies a duration on a Clock.

Attributes

- factor: Real [1] specifies the multiplicative factor to apply to duration.

Semantics

A Scaling is a special expression that denotes duration values obtained from a DurationValueSpecification by applying a multiplicative factor.

C.2.1.11 Span

A Span is a special expression that denotes duration values characterized by two instants (begin and end) on a Clock.

Generalizations

- DurationValueSpecification (from CVS)

Associations

- begin: InstantValueSpecification [1] specifies an instant origin of a time interval on a Clock.
- end: InstantValueSpecification [1] specifies an instant end of a time interval on a Clock.

Attributes

- none

Semantics

A Span is a special expression that denotes duration values characterized by two instants (begin and end) on a Clock.

C.2.1.12 Translation

A Translation is a special expression that denotes instant values obtained by a forward or backward translation of instants on a Clock.

Generalizations

- InstantValueSpecification (from CVS)

Associations

- offset: DurationValueSpecification [1]
specifies a duration that indicates the delay applied to the start instant on a Clock.
- start: InstantValueSpecification [1]
specifies an instant which is delayed on a Clock.

Attributes

- isBackward: Boolean [0..1]
indicates whether the instant translation is forward (isBackward not defined or defined and set to false) or backward (isBackward set to true).

Semantics

A Translation is a special expression that denotes instant values obtained by a forward or backward translation of instants on a Clock.

C.2.2 Concrete syntax

CVSL is a simple language for specifying clocked values (instant or duration) in MARTE. The language is not normative. For time expressions on a unique ChronometricClock, VSL::TimeExpressions (Annex B) can be used as well.

A character set encoding is assumed, supporting at least the alpha and the numeric classes, and possibly a miscSymbol class. Classically,

```
alpha ::= ('A' .. 'Z') | ('a' .. 'z')
```

```
numeric ::= '0' .. '9'
```

```
alphanumeric ::= alpha | numeric
```

And for the miscSymbol class, contains a possibly empty set of symbols useful to represent physical units. For instance,

```
miscSymbol ::= '°' | 'O' | ...
```

The syntax of the language reflects the domain view defined in the CVS package.

C.2.2.1 Literals

CVSL reuses number literals of VSL

```
number-literal ::= integer-literal | unlimited-natural | real-literal
```

```
integer-literal ::= ('+' | '-')? ( decimal-string | hexadecimal-string | binary-string )
```

```
unlimited-natural ::= unlimited-string
```

```
real-literal ::= ('+' | '-')? nonNegative-real-literal
```

```
nonNegative-real-literal ::= ( real-string | scientific-real )
```

```
scientific-real ::= real-string 'E' ('+' | '-')? decimal-string
```

```
real-string ::= decimal-string ('.' decimal-string)?
```

```
hexadecimal-string ::= '0x' ( ('0'..'9') | ('A'..'F') | ('a'..'f') )+
```

```
binary-string ::= '0b' ( '0' | '1' )+
```

```
decimal-string ::= ('0'..'9')+
```

```
unlimited-string ::= ( ('0'..'9')+ | '*' )
```

C.2.2.2 String literal

```
string-literal ::= ''' ( body-text | '(\\)' | '\\\\' )* '''
```

body-text ::= (terminal symbol consisting of string of characters defined in a character set encoding)

C.2.2.3 Identifiers

```
ident ::= ( alpha | '_' ) ( alphanumeric )*
```

In the rules, other non-terminals are can be used in place of ident to point out semantic differences (e.g., clockId , itemId...).

```
clockId ::= ident
```

```
itemId ::= ident
```

```
unitId ::= miscSymbol | (miscSymbol)? ident
```

C.2.2.4 Intervals

Intervals are used to specify a range of values. They are borrowed from VSL.

```
interval ::= ('[' | '[') value-specification '..' value-specification ('[' | '[')
```

C.2.2.5 Expressions

CVSL does not make full use of the VSL expressions. `value_specification` from VSL are restricted to Boolean expressions (`boolExpr`), integer expressions (`intExpr`), real expressions (`realExpr`) and use of variables.

C.2.2.6 Operators

CVSL considers a restricted set of operators. This set might be extended in the future if new operations are needed.

```
addOp ::= '+' | '-'
```

```
prefixOp ::= 'min' | 'max'
```

C.2.2.7 Clocked Value Specification

```
clockedValueSpecification ::= TimedValueSpecification
```

```
| ('{' TimedValueSpecification '}' unitId 'on' clockId )
```

```
TimedValueSpecification ::= duration | instant
```

duration specifications

```
duration ::= durTerm ( addOp durTerm )*
```

```
durTerm ::= ( 'mult' '(' realExpr ',' durFactor ')' ) | durFactor
```

```
durFactor ::= durationValue | durFunc | durationInterval
```

In this simple version only min and max operations are available.

```
durFunc ::= prefixOp '(' duration (',' duration)* ')' | span
```

span specifies duration by two instant specifications:

```
span ::= 'durationBetween' '(' instant ',' instant ')'
```

instant specifications

```
instant ::= instFactor addOp duration | instFactor
```

```
instFactor ::= instantValue | instantFunc | instantInterval | '(' instant ')'
```

An instant can be specified as the sum or the difference of an instant specification and a duration specifications. An instant can also be specified by a more general expression. In this simple version only min and max operations are available.

```
instantFunc ::= prefixOp '(' instant (',' instant)* ')'
```

C.2.2.8 TimeInstanceValue

Two syntactic forms are available for denoting TimeInstanceValue. This first one uses the tuple notation, as VSL does. The second is closer to a natural language expression.

```
timeInstanceValue ::= '(' valOrExpr ',' unitSpec (',' clockSpec)? ')'  
                    | realValue unitId 'on' clockId
```

```
valOrExpr ::= ('value' '=' realValue) | ('expr' '=' realExpr)
```

```
unitSpec ::= 'unit' '=' unitId
```

```
clockSpec ::= 'onClock' '=' clockId
```

```
realValue ::= nonnegative-real-literal | variable-name
```

The tuple form denotes either an instance of an NFP_duration (from BasicNFP_Types) or an instance of a TimedValueType (from TimeLibrary). The former can be used only for the idealClk, which is implicit in the notation. variable-name is defined in the VSL grammar.

instantInstanceValue and durationInstanceValue are both timeInstanceValue. The evaluation context determines the interpretation of the value.

```
instantInstanceValue ::= timeInstanceValue
```

```
durationInstanceValue ::= timeInstanceValue
```

C.2.3 Examples of clocked value specifications

C.2.3.1 Single clock time values

The three specifications below denote the same time instance value, on the idealClk clock.

```
(value = 1.5, unit = ms)
```

```
(value = 1.5, unit = ms, onClock = 'idealClk')
```

```
1.5 ms on idealClk
```

The first two specifications use the tuple notation. In the first one (NFP_Duration) the clock is implicitly the idealClk clock. The last one avoids item identifiers, parentheses, commas and single quotes.

C.2.3.2 Simple expressions on a single clock

```
(value = 1, unit = ms) + (value = 150, unit = us)
```

This expression is implicitly on the idealClk clock. Its value is (value = 1.150, unit = ms) or (value = 1150, unit = us), value obtained after applying the conversion factor between ms and us (1 ms = 1000 us). Any clock other than idealClk must be explicitly given.

C.2.3.3 Expressions on multiple clocks

```
min (15 tick on prClk, 5 ms on idealClk)
```

This expression is an expression referencing two clocks. It is not always computable. A `ClockConstraint` binding the two clocks `prClk` and `idealClk` must be provided (e.g., the duration of a processor cycle).

```
{min (15 tick on prClk, 5 ms on idealClk)} ms on idealClk
```

The same expression placed in a context as above, must return a time value on `idealClk` and with `ms` for unit (if it is computable).

C.3 Clock Constraint Specification

C.3.1 Domain view

A `ClockConstraintSpecification` (CCS) consists of a non empty set of conditional constraints. Conditional means that the constraint is imposed only when the associated guard evaluates to true. In the absence of guard, the constraint is unconditionally applied.

Clock constraints are specialized into `ClockRelation`, `InstantRelation`, and `ChronoNFP`. An `InstantRelation` imposes an ordering or a coincidence between two instants of different clocks. A `ClockRelation` is more general and imposes constraints on set of instants of different clocks. A `ChronoNFP` is a constraint that applies to chronometric clocks only, and specifies time related non functional properties for a chronometric clock or a group of chronometric clocks. A fourth clock constraint is a `ClockDefinition`. It defines a new clock, local to the `ClockConstraintSpecification`.

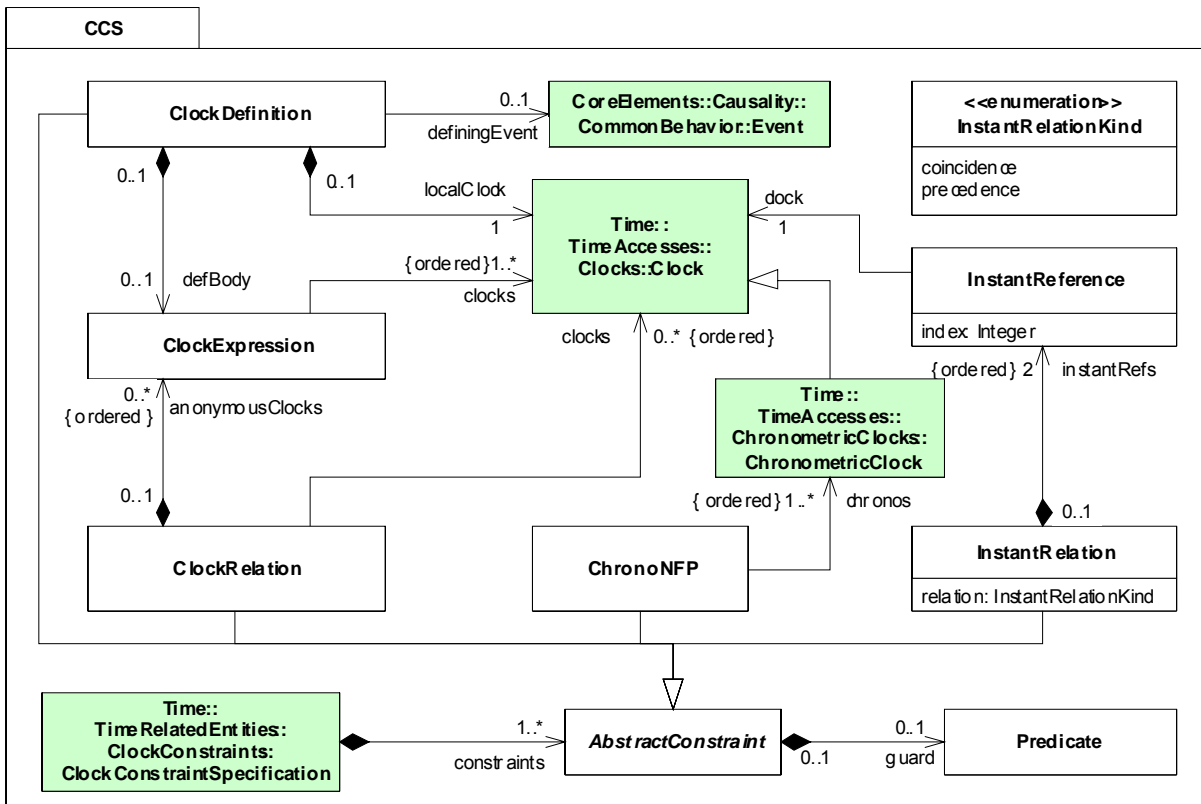

Figure C.2 - CCS domain view

C.3.1.1 AbstractConstraint

AbstractConstraint is an abstract super class of ClockRelation, ChronoNFP, InstantRelation, and ClockDefinition.

Generalizations

- None

Associations

- guard: Predicate [0..1]
 an owned predicate, which is evaluated in the context of the owning ClockConstraintSpecification. When this property is empty or when it is defined and evaluates to true, the constraint is applied. It is ignored otherwise.

Attributes

- None

Semantics

AbstractConstraint is an abstract super class of ClockRelation, ChronoNFP, InstantRelation, and ClockDefinition. The optional guard attribute indicates whether the constraint is applied or ignored according to the context of the ClockConstraintSpecification.

C.3.1.2 ChronoNFP

A ChronoNFP is a constraint that applies to chronometric clocks only, and specifies time related non functional properties for a chronometric clock or a group of chronometric clocks.

Generalizations

- AbstractConstraint (from CCS)

Associations

- `chronos:Time::TimeAccesses::ChronometricClocks::ChronometricClock[1..*]`
references a set of chronometric clocks whose time related non functional properties are constrained.

Attributes

- None

Semantics

A ChronoNFP is a constraint that applies to chronometric clocks only, and specifies time related non functional properties for a chronometric clock or a group of chronometric clocks.

Examples of ChronoNFP

- StabilityConstraint, which imposes a constraint on the value of the stability attribute of a ChronometricClock. Additional constraint: `chronos->size() = 1`.
- SkewConstraint, which imposes a constraint on the value of the skew attribute of a ChronometricClock, with respect to another ChronometricClock. Additional constraint: `chronos->size() = 2`.
- DriftConstraint, which imposes a constraint on the value of the drift attribute of a ChronometricClock, with respect to another ChronometricClock. Additional constraint: `chronos->size() = 2`.
- OffsetConstraint, which imposes a constraint on the value of the offset attribute of a ChronometricClock, with respect to another ChronometricClock. Additional constraint: `chronos->size() = 2`.

C.3.1.3 ClockDefinition

A ClockDefinition defines a new clock, local to the ClockConstraintSpecification.

Generalizations

- AbstractConstraint (from CCS)

Associations

- `defBody: ClockExpression[0..1]`
owned `ClockExpression` that specifies the `localClock` as derived from other clocks.
- `definingEvent: CoreElements::Causality::CommonBehavior::Event[0..1]`
references the event whose occurrences define the ticks of the `localClock`.
- `localClock: Time::TimeAccesses::Clocks::Clock[1]`
references the defined clock.

Attributes

- None

Semantics

A `ClockDefinition` defines a new clock, local to the `ClockConstraintSpecification`. This clock is defined as derived from other clocks or from occurrences of an event.

Constraints

[2] A (local) clock can be defined either by a `ClockExpression` or by an `Event`.

`definingEvent->notEmpty() = defBody->isEmpty()`

C.3.1.4 ClockExpression

A `ClockExpression` specifies a clock derived from one or many clocks.

Generalizations

- None

Associations

- `clocks: Clock [1..*] { ordered }`
references the clocks from which the specified clock is derived.

Attributes

- None

Semantics

A `ClockExpression` specifies a clock derived from one or many clocks.

Examples of `ClockExpression`

A `ClockExpression` is a function-like clock relation which returns a `Clock` derived from other clocks.

- `ClockDiscretization`, takes a dense `ChronometricClock`, and returns a discrete `Clock`. Parameters: a `discretizationStep`, and an optional `discretization interval`.
- `ClockFiltering`, derives a discrete clock from another discrete clock. Each instant of the returned clock is coincident with an instant of the filtered clock. Parameter: a `BinaryWord` which specifies the filter: the `kth` instant of the filtered

clock is coincident with an instant of the returned clock if and only if the k th bit of the BinaryWord is set to 1.

- ClockDelay, takes a clock and returns a new one. Parameter: a delay. The k th instant of the returned clock is coincident with the $(k+\text{delay})$ th instant of the given clock.
- ClockChaining, takes two clocks and returns a new one. The first argument clock must be finite. The first instants of the returned clock are coincident with the instants of the first clock. The following instants are coincident with the instants of the second clock.

Figure C.17.30 illustrates clock expressions. Junction instants are represented by small circles, and the coincidence relation by red edges between junction instants.

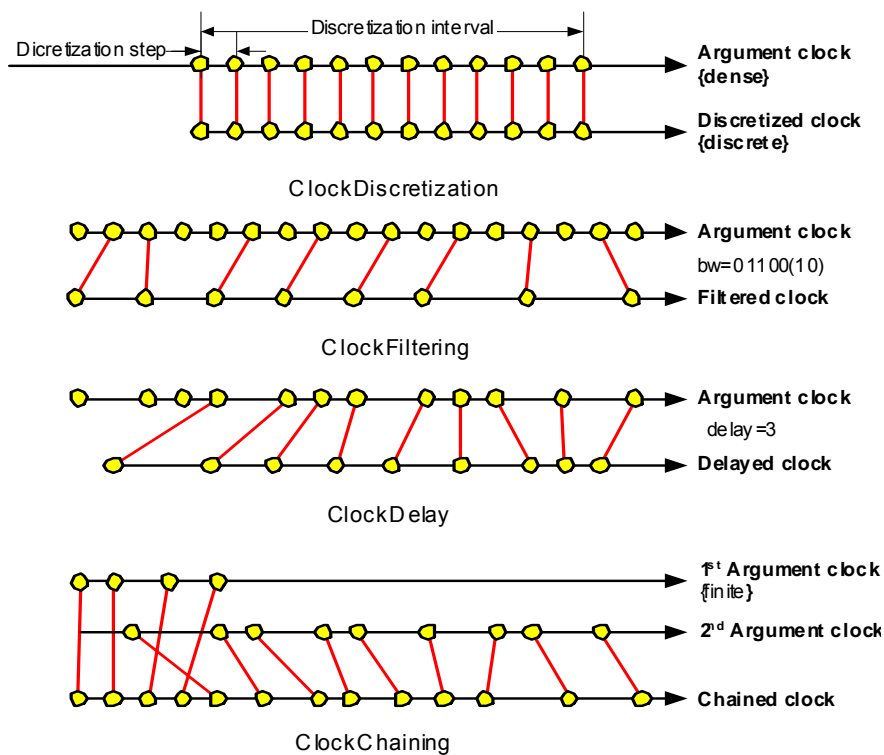

Figure C.3 - Examples of clock expressions

C.3.1.5 ClockRelation

A ClockRelation specifies a constraint among clocks. This constraint imposes relations between instants of those clocks.

Generalizations

- AbstractConstraint (from CCS)

Associations

- anonymousClocks: ClockExpression [0..*]
 references clock expressions involved in the relation. They are called anonymous clocks because they are not identified clocks, but clock expressions specifying an unnamed clock. The clock

expressions are owned by this ClockRelation.

- clocks: Clock [0..*]references clocks involved in the relation.

Attributes

- None

Semantics

A ClockRelation specifies a constraint among clocks. This constraint imposes relations (coincidence or precedence) between instants of those clocks.

Constraints

[1] A ClockRelation constrains at least two clocks or anonymous clocks.

```
clocks->union(anonymousClocks)->size( ) >= 2
```

Examples of ClockRelation

A ClockRelation is a relational dependency between instants of clocks. This is a more general concept than ClockExpression which is a functional dependency. A ClockRelation imposes a partial ordering between the instants of the clocks. In what follows, ClockReference denotes either a Clock or a ClockExpression.

The following clock relations constrain a pair of ClockReferences.

- Periodicity imposes that there exists an integer p such that between each pair of successive instants of a ClockReference, there exist p instants of the other ClockReference.
- Sporadicity imposes that there exists an integer g such that between each pair of successive instants of a ClockReference, there exist at least g instants of the other ClockReference.
- Subclocking imposes that there exists an injective mapping from the instants of one ClockReference onto the instants of the other ClockReference, such that this mapping preserves the instant ordering. This relation is a weak form of the ClockFiltering without an imposed filter.
- Equality is a strong relation: there exists a one-to-one mapping between instants of the two ClockReferences, and this mapping is order preserving.

Some clock relations require a third ClockReference. Each constrained ClockReference must be subclock of this third ClockReference.

- RelativeSpeed imposes that for any integer k , the k th instant of the faster ClockReference precedes the k th instant of the slower ClockReference.
- MaximalDrift imposes that there exists an integer m such that for each instant k of the third ClockReference, the absolute difference between the numbers of instants preceding instant k in the two ClockReferences is less than or equal to m .

Figure C.17.31 illustrates clock relations. Note that junction instants are not necessarily evenly interspaced.

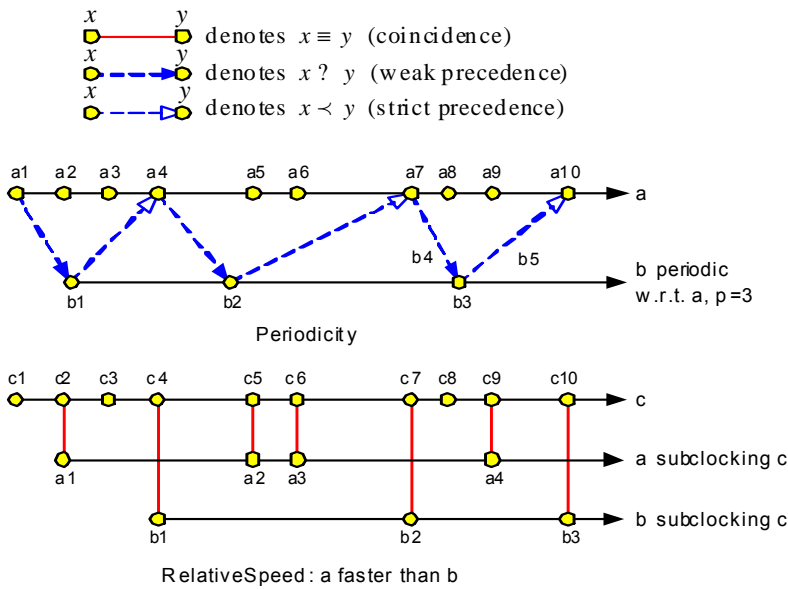

Figure C.4 - Examples of clock relations

C.3.1.6 InstantReference

An InstantReference specifies an instant of a Clock.

Generalizations

- None

Associations

- clock: Clock [1] references the Clock whose instant is referred to.

Attributes

- index: Integer [1] specifies the index of the instant.

Semantics

An InstantReference specifies an instant of a Clock.

C.3.1.7 InstantRelation

An InstantRelation imposes a precedence or a coincidence constraint between two instants of two different clocks.

Generalizations

- AbstractConstraint (from CCS)

Associations

- `instantRefs: InstantReference [2] {ordered}`
specifies two owned InstanceReferences. The order is significant for the precedence relation.

Attributes

- `relation: InstantRelationKind [1]`
specifies whether the constraint between the constrained instants is a coincidence or a precedence.

Semantics

An InstantRelation imposes a precedence or a coincidence constraint between two instants of two different clocks.

Constraints

[1] The referenced instants belong to different clocks.

```
instanceRefs.clock->size( ) = 2
```

C.3.2 CCSL concrete syntax

CCSL is a purely declarative language for expressing constraints on MARTE's Clocks. The proposed concrete syntax has been chosen to be close enough to the English language. It is not normative.

A character set encoding is assumed, supporting at least the alpha and the numeric classes. Classically,

```
alpha ::= ('A' .. 'Z') | ('a' .. 'z')
```

```
numeric ::= '0' .. '9'
```

```
alphanumeric ::= alpha | numeric
```

The syntax of the language reflects the domain view defined in the CCS package.

C.3.2.1 Literals

CCSL reuses number literals of VSL

```
number-literal ::= integer-literal | unlimited-natural | real-literal
```

```
integer-literal ::= ('+' | '-')? ( decimal-string | hexadecimal-string | binary-string )
```

```
unlimited-natural ::= unlimited-string
```

```
real-literal ::= ('+' | '-')? ( real-string | scientific-real )
```

```
scientific-real ::= real-string 'E' ('+' | '-')? decimal-string
```

```
real-string ::= decimal-string ('.' decimal-string)?
```

```
hexadecimal-string ::= '0x' ( ('0'..'9') | ('A'..'F') | ('a'..'f') )+
```

```
decimal-string ::= ('0'..'9')+
```

```
unlimited-string ::= ( ('0'..'9')+ | '*' )
```

CCSL adds new literals for BitVectors and BinaryWords. A BitVector is a sequence of bits; a BinaryWord is a pair of BitVectors consisting of a prefix and a period. Two concrete notations are provided: a flat notation starting with the `0b` prefix, and notation with repetition factors starting with the `0B` prefix.

```

bit ::= '0' | '1'
bitv ::= '0b' ( (bit)+ ('(' (bit)+' )'? ) | ('(' (bit)+' )' )
rbit ::= bit ('^' ('1'..'9') ('0'..'9')* )?
gbitv ::= rbit ('.' (rbit))*
gbw ::= '0B' ( (gbitv)+ ('(' gbitv ')')'? ) | ('(' gbitv ')') )
bw ::= bitv | gbw

```

Examples of BinaryWords:

0b100(1100) denotes the binary word whose prefix is 100 and whose period is 1100. In turn, this binary word denotes the infinite bit vector 100110011001100....1100...

0B1.0²(1².0²) denotes the same binary word (useful notation when the exponent is big).

0b(100) denotes the binary word whose prefix is empty and whose period is 100.

0b110 denotes the binary word whose prefix is 110 and whose period is empty. Thus, this binary word denotes the finite bit vector: 110.

Note that 0b(0) an infinite sequence of 0, not the empty BitVector.

C.3.2.2 Identifiers

```
ident ::= ( alpha | '_' ) ( alphanumeric )*
```

In the rules, other non-terminals are can be used in place of ident to point out semantic differences (e.g., clockId , itemId...).

```
clockId ::= ident
```

```
itemId ::= ident
```

```
instantId ::= ident
```

C.3.2.3 Intervals

Intervals are used to specify a range of values. They are borrowed from VSL.

```
interval ::= ('[' | ']') value-specification '..' value-specification ('[' | ']')
```

C.3.2.4 Tuples

Tuples are convenient for representing structured data values. They are also from VSL.

```
tuple ::= '(' ( itemId '=' )? value_specification (',' ( itemId '=' )? value_specification )* ')'
```

C.3.2.5 Expressions

CCSL does not make full use of the VSL expressions. `value_specification` from VSL are restricted to Boolean expressions (`boolExpr`), integer expressions (`intExpr`), real expressions (`realExpr`).

CCSL adds its own duration expression:

```
durationExpr ::= realExpr unitId 'on' clockId
```

C.3.2.6 Operators

CCSL has relational operators, Boolean operators, and the dot operator used for navigation à la OCL.

```
relOp      ::= '<' | '<=' | '=' | '>=' | '>' | '<>' | 'in'
```

```
booleanOp ::= 'and' | 'or' | 'xor' | 'not'
```

```
path      ::= id ( '.' id ) *
```

C.3.2.7 Constraints

A clock constraint consists of a set of conditional statements.

```
clockConstraint ::= ( conditionalStatement ';' ) +
```

```
conditionalStatement ::= statement (guard)?
```

```
statement ::= clockDef | instantRel | clockRel | chronoNFP | instantDef
```

```
guard ::= 'if' boolExpr
```

```
clockDef ::= 'Clock' clockId ( 'is' clockExpr )?
```

```
clockRef ::= clockId | '(' clockExpr ')'
```

```
instantDef ::= 'Instant' instantId ( 'is' instantRef )?
```

```
instantRef ::= instantId | ( clockRef '[' intExpr ']' )
```

```
| 'instantOf' clockRef 'suchThat' boolExpr
```

C.3.2.8 ChronoNFP

Time-related non functional properties of ChronometricClocks have been defined in the CCS domain view. The chosen syntax is self-explanatory.

```
chronoNFP ::= clockRef  
            ( ( 'hasStability' realExpr ) ('wrt' clockId )?  
              | ( ',' clockRef  
                  ( ('haveSkew'|'haveDrift') realExpr )  
                  | ('haveOffset' durationExpr )  
                  ) ('wrt' clockId )? ('at' instantExpr )?  
            )  
            )
```

C.3.2.9 Clock expressions

A ClockExpression specifies a clock derived from one or many clock references.

```
clockExpr ::= clockId
           | ( 'when' eventExpr )
           | clockRef
           ( ( 'restrictedTo' boolExpr )
             | ( 'filteredBy' bwExpr )
             | ( 'discretizedBy' realExpr
               ('from' realExpr )? ('to' realExpr )? )
             | ( 'delayedBy' intExpr )
             | ( 'followedBy' | 'inter' | 'minus' | 'sampledTo' )
             clockRef
           )
```

C.3.2.10 Clock relations

The ClockRelations have been defined in the CCS domain view.

```
clockRel ::= clockRef
          ( ( ('isPeriodicOn' clockRef ('period' realExpr )?)
            | ('isSporadicOn' clockRef ('gap' realExpr )?)
            | ( ( 'isFinerThan' | 'isCoarserThan' ) clockRef )
            | ( ( 'isFasterThan' | 'isSlowerThan' ) clockRef )
            | ( ',' clockRef 'haveMaxDrift' intExpr )
            | ( '=' clockRef )
            | ( '#' clockRef )
            | ( 'alternatesWith' clockRef )
            | ( 'hasSameRateThan' clockRef )
          )
```

C.3.2.11 Instant relations

The reference to an instant of a given Clock is made using the at operation.

```
instant ::= clockId '.' 'at' '(' intExpr ')'
```

```
instantRel ::= instantRef
            ( 'coincidentWith' | ('strictly')? 'precedes' )
            instantRef
```

Periodicity and Sporadicity are respectively denoted by isPeriodicOn and isSporadicOn. The optional real expression allows the user to specify the period or the minimal gap between successive instants of the first clock with respect to the second.

Subclocking is denoted by isCoarserThan. The converse is also offered if b isCoarserThan a, then a isFinerThan b. b is a subclock of a, and a is a superclock of b.

RelativeSpeed is expressed by isFasterThan, with the converse relation isSlowerThan.

Equality is simply denoted by the equality symbol.

The maximalDrift relation being symmetric, the adopted syntax is a pair of clock references followed by haveMaxDrift. This yields an integer value which is constrained.

Annex D: Normative MARTE Model Libraries (MARTE_Library)

D.1 MARTE Model Library for Primitive Types

This section defines a model library of MARTE primitive types (Figure D.1) that includes predefined operations commonly used in the real-time and embedded system domain.

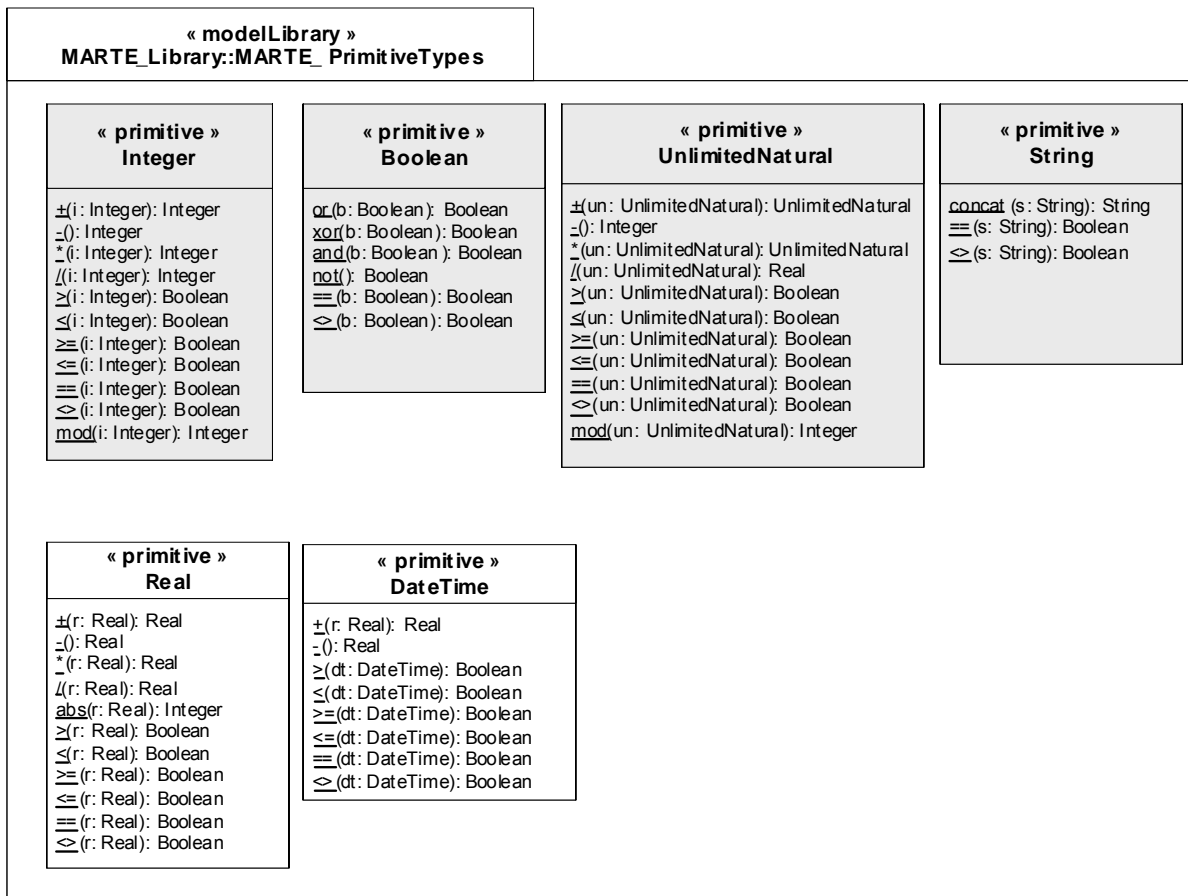

Figure D.1 - MARTE Primitive types and their operators

For each operation the signature and a description of the semantics is given in the following sub-headings. Within the description, the reserved word 'result' is used to refer to the value those results from evaluating the operation. Note that all the defined operations are static.

D.1.1 Real

The standard type Real represents an approximation to the mathematical concept of real. Note that Integer is a subclass of Real, so for each parameter of type Real, you can use an integer as the actual parameter.

+ (r : Real) : Real	value of the addition of self and r.
- () : Real	negative value of self.
* (r : Real) : Real	value of the multiplication of self and r.
/ (r : Real) : Real	value of self divided by r.
abs() : Real	absolute value of self.
< (r : Real) : Boolean	true if self is less than r.
> (r : Real) : Boolean	true if self is greater than r.
<= (r : Real) : Boolean	true if self is less than or equal to r.
>= (r : Real) : Boolean	true if self is greater than or equal to r.
<> (r : Real) : Boolean	true if different to r.
== (r : Real) : Boolean	true if equal to r.

D.1.2 Integer

The standard type Integer represents the mathematical concept of integer.

+ (i : Integer) : Integer	value of the addition of self and i
- () : Integer	negative value of self
* (i : Integer) : Integer	value of the multiplication of self and i.
/ (i : Integer) : Real	value of self divided by i
< (i : Integer) : Boolean	true if self is less than i.
> (i : Integer) : Boolean	true if self is greater than i.
<= (i : Integer) : Boolean	true if self is less than or equal to i.
>= (i : Integer) : Boolean	true if self is greater than or equal to i
<> (i : Integer) : Boolean	true if different to i
== (i : Integer) : Boolean	true if equal to i
mod (i : Integer) : Integer	true modulo of self and i

D.1.3 Unlimited Natural

The standard type Unlimited Natural represents the mathematical concept of Natural including the infinite value.

+ (un : UnlimitedNatural) : UnlimitedNatural	value of the addition of self and un
- () : Integer	negative value of self.
* (un : UnlimitedNatural) : UnlimitedNatural	value of the multiplication of self and u
/ (un : UnlimitedNatural) : Real	value of self divided by un
< (un : UnlimitedNatural) : Boolean	true if self is less than un
> (un : UnlimitedNatural) : Boolean	true if self is greater than un.
<= (un : UnlimitedNatural) : Boolean	true if self is less than or equal to un
>= (un : UnlimitedNatural) : Boolean	true if self is greater than or equal to un
<> (un : UnlimitedNatural) : Boolean	true if different to un.
== (un : UnlimitedNatural) : Boolean	true if equal to un
mod (un : UnlimitedNatural) : Integer	true modulo of self and i

D.1.4 String

The standard type String represents strings, which can be both ASCII and Unicode.

concat(s : String) : String	concatenation of self and s
<> (s : String) : Boolean	true if different to s.
== (s : String) : Boolean	true if equal to s.

D.1.5 Boolean

The standard type Boolean represents the common true/false values.

or (b : Boolean) : Boolean	true if either self or b is true
xor (b : Boolean) : Boolean	true if either self or b is true, but not both
and (b : Boolean) : Boolean	true if both self and b are true
not () : Boolean	true if self is false.
<> (b: Boolean) : Boolean	true if different to b
== (b: Boolean) : Boolean	true if equal to b

D.1.6 DateTime

Datetime defines an instant of time in calendar format.

+ (r : Real) : Real	value of the addition of self and r, after converting DateTime to real.
- (r : Real) : Real	value of the subtraction of r to self, after converting DateTime to real
< (dt : DateTime) : Boolean	true if self is less than dt.
> (dt : DateTime) : Boolean	true if self is greater than dt.
<= (dt : DateTime) : Boolean	true if self is less than or equal to dt
>= (dt : DateTime) : Boolean	true if self is greater than or equal to dt.
<> (dt : DateTime) : Boolean	true if different to dt.
== (dt : DateTime) : Boolean	true if equal to dt

D.2 MARTE model library for extended datatypes

This section defines the complete set of MARTE datatypes that use the UML profiles for NFP and VSL. In figure D.1, we show the whole architecture of extended data types and the applied profiles.

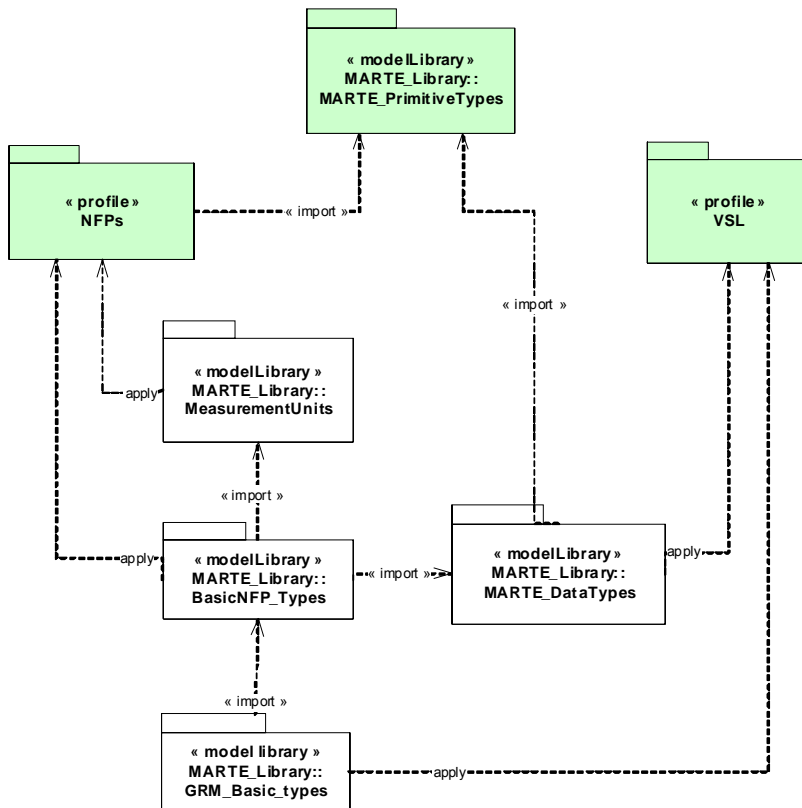

Figure D.2 - Structure of the MARTE time model library

The following four figures show the internals of the concerned four packages. The semantics and usage of the pre-defined datatypes is stated in each of the chapter that uses them.

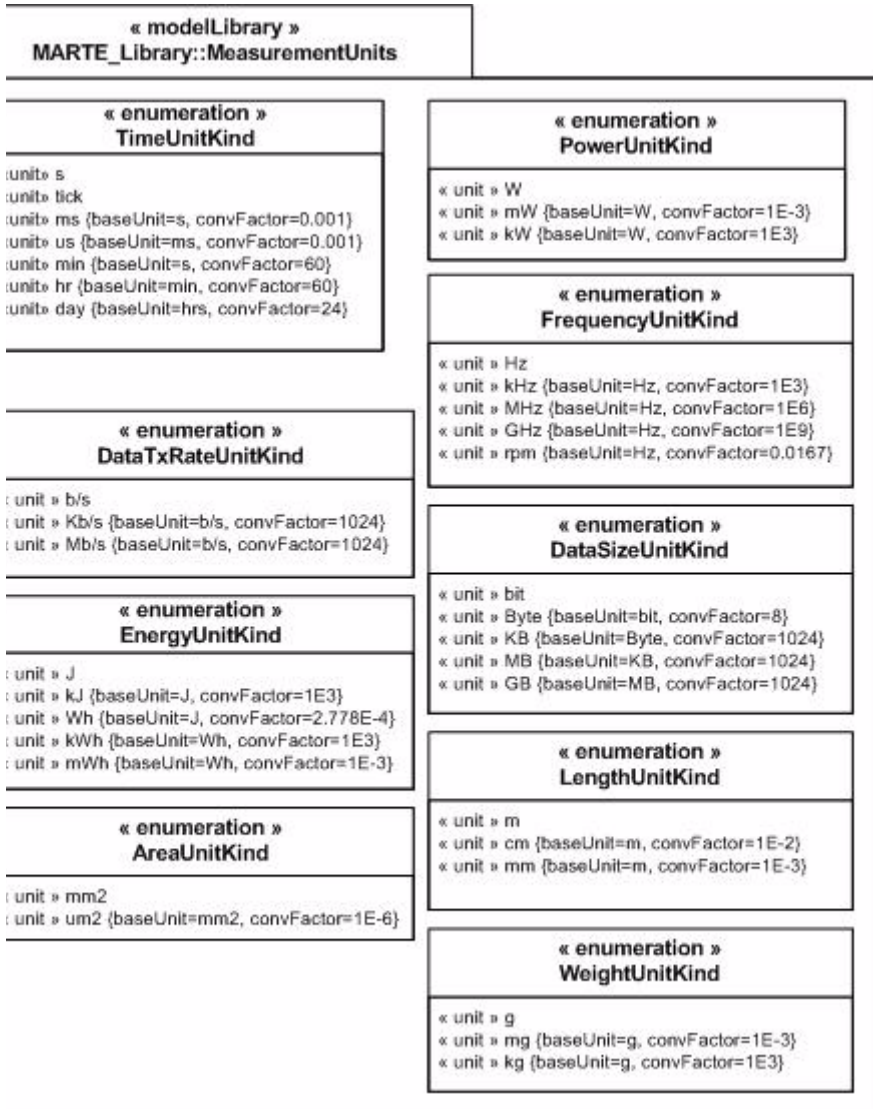

Figure D.3 - MARTE library of measurement units

Figure D.4 - MARTE library of general data-types

D.2.1 TransmModeKind

This enumeration defines the kind of transmission mode of messages over a network.

Literals

- simplex it allows for one-way communication of data through the network.
- half-duplex it allows communication in both directions, but only one direction at a time (not simultaneously). Typically, once a party begins receiving a signal, it must wait for the transmitter to stop transmitting, before replying.
- full-duplex it allows communication in both directions, and unlike half-duplex, allows this to happen simultaneously.

Figure D.5 - MARTE library of pre-declared NFP types

D.2.2 ArrivalPattern

This is a ChoiceType that contains the different kinds of parameters that are necessary to specify the most common arrival patterns of events.

Attributes

- periodic: PeriodicPattern [0..1] it describes periodic interarrival patterns, with an optional maximal deviation (jitter).
- aperiodic: AperiodicPattern [0..1] it describes an unbounded pattern that is defined by a distribution function
- sporadic: AperiodicPattern [0..1] it describes a bounded pattern that is defined by a corner case interarrival times and a maximum deviation (jitter)
- burst: BurstPattern [0..1] it describes a bursty interarrival pattern with a number of events that can occur in a bounded period.
- irregular: IrregularPattern [0..1] it describes an aperiodic pattern that is described by a table of successive interarrivals durations measured from a starting phase.
- closed: ClosedPattern [0..1] it describes a workload characterized by a fixed number of active or potential users or jobs that cycle between executing the scenario.
- open: OpenPattern [0..1] it describes a workload that is modeled as a stream of requests that arrive at a given rate in some predetermined pattern (such as Poisson arrivals).

D.2.3 PeriodicPattern

This is a TupleType that contains the parameters that are necessary to specify a periodic pattern.

Attributes

- period: NFP_Duration [0..1] the period as a duration.
- jitter: NFP_Duration [0..1] the maximum deviation of the occurrences
- phase: NFP_Duration [0..1] a delay for the first occurrence of the event.
- occurrences: NFP_Integer [0..1] the maximum number of occurrences of the periodic arrival event.

D.2.4 AperiodicPattern

This is a TupleType that contains the parameters that are necessary to specify an aperiodic pattern (unbounded pattern).

Attributes

- distribution: NFP_CommonType [0..1] a distribution of the arrival pattern that could use one of the patterns described in Section 8.3.3.

D.2.5 SporadicPattern

This is a TupleType that contains the parameters that are necessary to specify a sporadic pattern (bounded pattern).

Generalizations

- AperiodicPattern.

Attributes

- minInterarrival: NFP_Duration [0..1] the minimum interarrival duration between two successive occurrences of an event.
- maxInterarrival: NFP_Duration [0..1] the maximum interarrival duration between two successive occurrences of an event.
- jitter: NFP_Duration [0..1] the maximum deviation of the occurrences regarding to the minimum interarrival time.

D.2.6 BurstPattern

This is a TupleType that contains the parameters that are necessary to specify a bursty pattern.

Generalizations

- AperiodicPattern.

Attributes

- minInterarrival: NFP_Duration [0..1] the minimum interarrival duration between two successive occurrences of an event.
- maxInterarrival: NFP_Duration [0..1] the maximum interarrival duration between two successive occurrences of an event.
- minEventInterval: NFP_Duration [0..1] the minimum interval between two occurrences within a burst.
- maxEventInterval: NFP_Duration [0..1] the maximum interval between two occurrences within a burst.
- burstSize: NFP_Integer the number of event occurrences within a burst.
- minEventInterval: NFP_Duration [0..1] the minimum interval between two occurrences within a burst.

D.2.7 IrregularPattern

This is a TupleType that contains the parameters that are necessary to specify an irregular pattern (list of duration separations between successive event occurrences). This is a fully deterministic arrival pattern.

Generalizations

- AperiodicPattern

Attributes

- phase: NFP_Duration [0..1] a delay for the first occurrence of the event.
- interarrivals: NFP_Duration[*] the set of duration separations between successive event occurrences.

D.2.8 ClosedPattern

This is a TupleType that contains the parameters that are necessary to specify a closed pattern. It is characterized by a fixed number of active or potential users or jobs that cycle between executing the scenario, and spending an external delay period (sometimes called "think time") outside the system, between the end of one response and the next request.

Attributes

- population: NFP_Integer [0..1] the size of the workload (number of system users).
- extDelay: NFP_Duration [0..1] the delay between the end of one response and the start of the next for each member of the population of system users

D.2.9 OpenPattern

A workload that is modeled as a stream of requests that arrive at a given rate in some predetermined pattern (such as Poisson arrivals).

Attributes

- interArrivalTime: NFP_Duration [0..1] the time between successive arrivals. For a Poisson process this is exponentially distributed with mean = 1/rate.
- arrivalRate: NFP_Frequency [0..1] the average rate of arrivals.
- arrivalProcess: String [0..1] the name of an arrival process, understood by the analysis tool. Examples (not exhaustive) are Poisson, General, Phase-type, Markov-Modulated Poisson, Correlated, Pareto. If arrivalProcess is defined, normally arrivalRate is also defined, and interArrivalTime is not.

D.3 MARTE model library for time

This section provides model elements related to Time, gathered in two model libraries (Figure D.6 on page 454). The TimeTypesLibrary library is used in the Time profile, the TimeLibrary is for users.

Figure D.6 - Structure of the MARTE time model library

D.3.1 TimeTypesLibrary Library

This package contains enumerations used in the *Time* profile (Figure D.7 on page 455). *TimeNatureKind* is an enumeration type that defines literals used to specify the discrete or dense nature of a time value. *TimeInterpretationKind* is an enumeration type that defines literals used to specify the way to interpret a time expression: either as a duration or as an instant.

The *EventKind* enumeration contains literals that may characterize events: events related to a behavior execution (start and finish), and events related to a stimulus (send, receive, and consume).

TimeStandardKind defines literals used to specify the standard “systems of time”. The meaning of the acronyms is given below:

- GPS General Positioning System, not adjusted for leap seconds
- Local Local Time
- Sidereal Sidereal Time
- TAI International Atomic Time scale, a statistical timescale based on a large number of atomic clocks
- TCB Barycentric Coordinate Time
- TCG Geocentric Coordinate Time
- TDB Barycentric Dynamical Time
- TT Terrestrial Time
- UT0 Universal Time 0
- UT1 Universal Time 1
- UTC Coordinated Universal Time

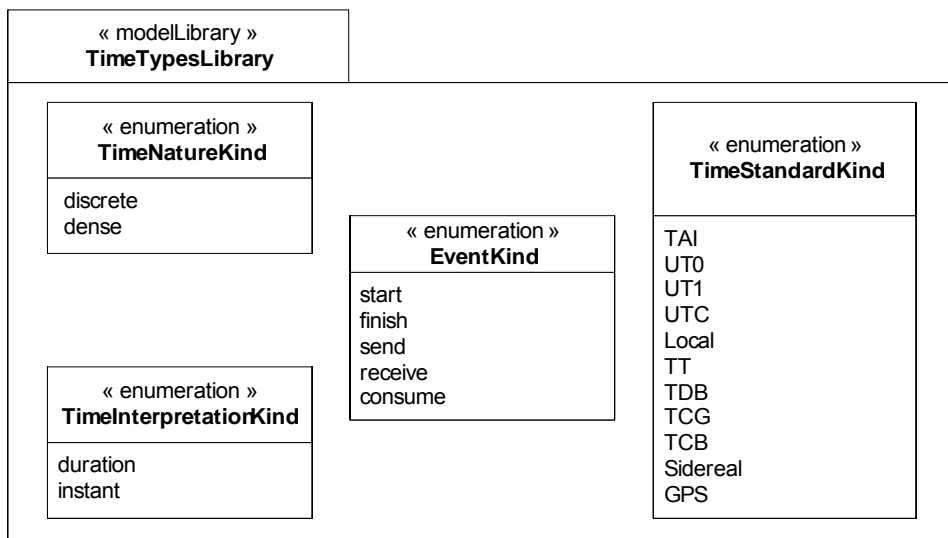

Figure D.7 – TimeTypesLibrary library

D.3.2 TimeLibrary

The TimeLibrary library (Figure D.8 on page 456) provides enumerations related to time and facilities for using the ideal chronometric time (*i.e.*, the time referenced in physical laws).

TimeUnitKind contains the main chronometric time units. *s* (second) is an SI unit. Other units are derived units. All the enumeration literals are stereotyped by *clockUnit*.

LogicalTimeUnitKind is a special enumeration which contains one enumeration literal only. This literal is *tick*.

The *IdealClock* and its instance *idealClk* model the abstract and ideal time which is used in physical laws. It is a dense time. *idealClk* should be imported in models that refer to chronometric time. *TimedValueType* is a templated data type. The template parameter is an enumeration which contains time units.

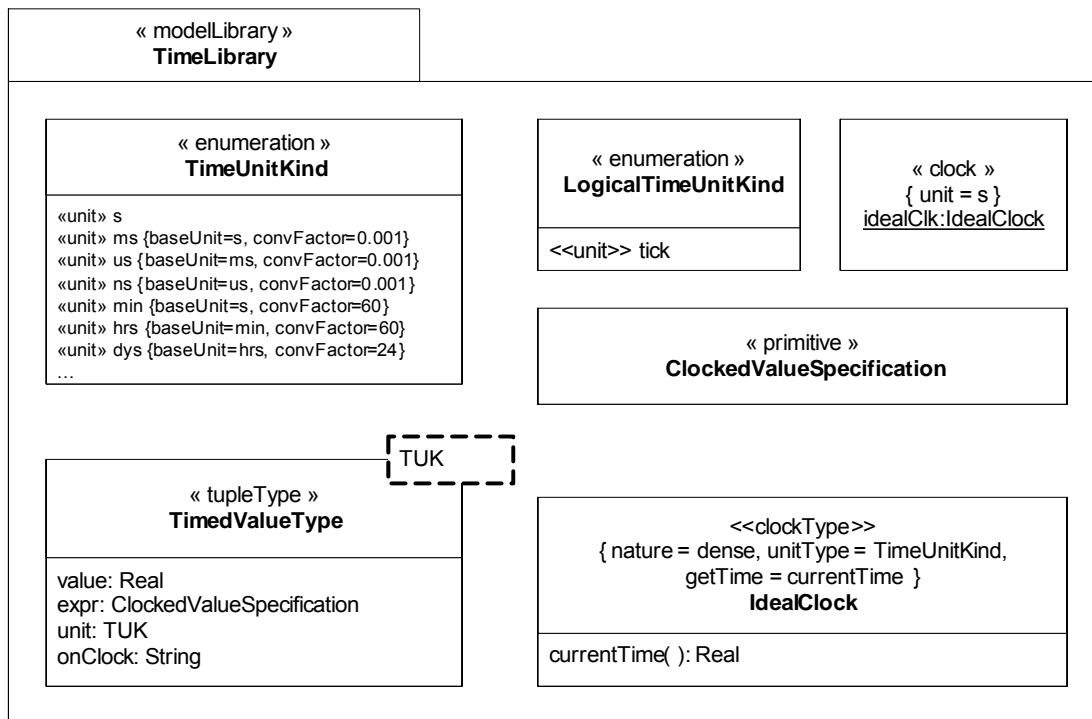

Figure D.8 - Detailed model library of TimeLibrary

D.4 MARTE model library for GRM

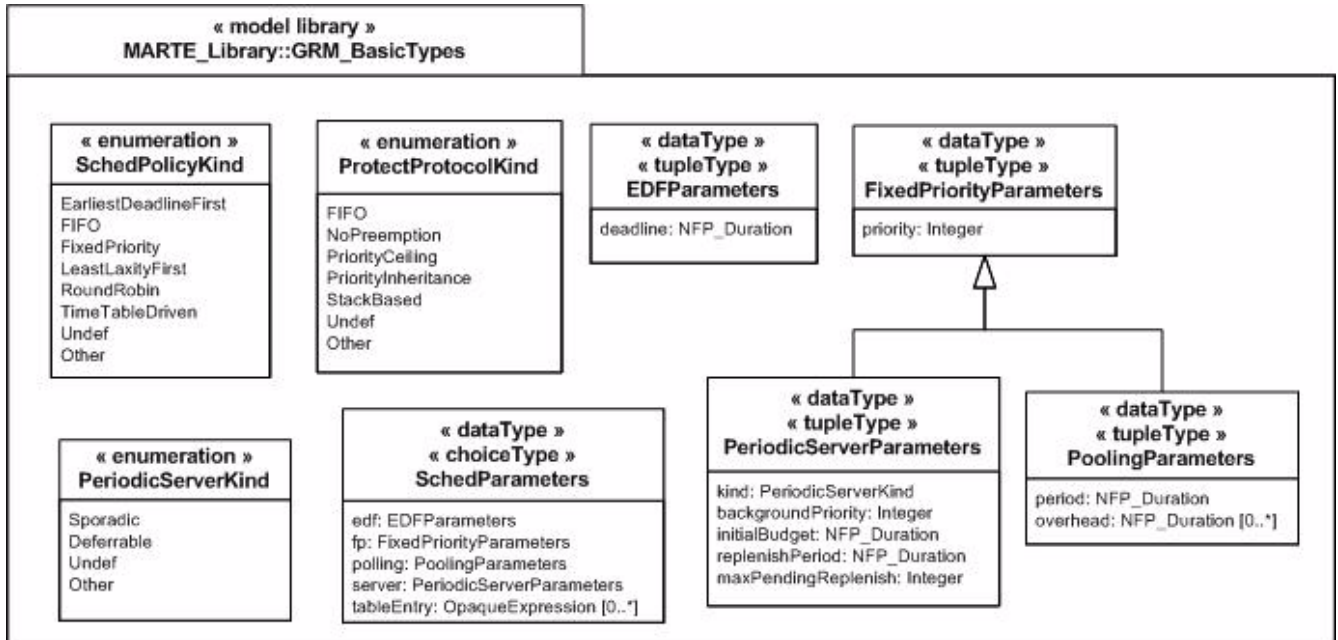

Figure D.9 - Details of the MARTE model library for GRM

D.4.1 EDF_Parameters

This dataType is a tupleType that defines the parameter used to characterize an EDF schedulable resource.

Attributes

- `deadline: NFP_Duration [0..1]` relative deadline used to schedule each activation of the schedulable resource in the context of an EDF scheduler.

D.4.2 FixedPriorityParameters

This dataType is a tupleType that defines the parameter used to characterize a fixed priority schedulable resource.

Attributes

- `priority: Integer [0..1]` priority used to schedule the schedulable resource in a fixed priority scheduler.

D.4.3 NoParams

This is an empty utility dataType used in choiceTypes to indicate the absence of a value.

D.4.4 PeriodicServerKind

This enumeration defines the kind of periodic server.

Literals

- `sporadic` indicates the sporadic server scheduling algorithm.
- `deferrable` indicates the deferrable server scheduling algorithm.
- `undef` indicates the scheduling algorithm of the server is not defined.
- `other` the scheduling algorithm of the server is none of the described in this enumerated.

D.4.5 PeriodicServerParameters

This is a TupleType that contains the scheduling parameters that are necessary to schedule the kinds of periodic servers defined.

Generalizations

- FixedPriorityParameters

Attributes

- `kind: PeriodicServerKind [0..1]`
indicates the type of periodic server.
- `backgroundPriority: Integer [0..1]`
is the priority used to run the server when it is in the background.
- `initialBudget: NFP_Duration [0..1]`
is the full amount of execution time available for a cycle of the server.
- `replenishPeriod: NFP_Duration [0..1]`
is the replenishment period defined for the server.
- `maxPendingReplenish: Integer [0..1]`
is the maximum number of replenishments that can be stored in the queue of pending replenishments, it limits the number of times a schedulable resource may block itself in the time frame of a cycle period.

D.4.6 PoolingParameters

This is a TupleType that contains the scheduling parameters that are necessary to schedule a schedulable resource with the polling policy kind. It represents the scheduling mechanism by which there is a periodic task that polls for the arrival of its input event. Thus, execution of the actions associated to the event may be delayed until the next period.

Generalizations

- FixedPriorityParameters

Attributes

- `period: NFP_Duration [0..1]`
is the polling period, the time between successive inquiries for the arrival of an activation event.

- overhead: NFP_Duration [0..*]
list of duration time values that characterize the polling overhead, it is typically characterized by the minimum, maximum and average values.

D.4.7 ProtectProtocolKind

This is an enumerated type that list the kinds of protection protocols to use in the access to shared resources. It corresponds to the homonymous concept of of the domain view, whose class description is described in Annex F.

Literals

- FIFO
this means basically exclusive access with no protection.
- NoPreemption
no other concurrent activity may be executed while the resource is in use
- PriorityCeiling
uses the immediate priority ceiling resource protocol. This is equivalent to Ada's Priority Ceiling, or the POSIX priority protect protocol. It requires the specification of an integer value to indicate the ceiling.
- PriorityInheritance
it uses the basic priority inheritance protocol.
- StackBased
it uses the Stack Resource Protocol (SRP). This is similar to the priority ceiling protocol but works for non-priority-based policies. It requires the specification of the preemption level.
- Undef
the protocol is not specified.
- Other
the protocol is not included in this enumerated type, but it is specified using a user-defined string.

D.4.8 SchedParameters

This is a ChoiceType that contains the different kinds of parameters that are necessary to specify the contention privileges of a schedulable resource in comparison to others unther the same scheduler. It maps to the SchedulingParameters concept of the domain view, whose class description is described in Annex F.

Attributes

- edf: EDF_Parameters [0..1]
parameters used in the arliest deadline first scheduling policy.
- fp: FixedPriorityParameters [0..1]
parameters used in the fixed priority scheduling policy.
- polling: PollingParameters [0..1]
parameters used when a polling mechanism is used to start schedulable resources running under a fixed priority scheduling policy.
- server: PeriodicServerParameters [0..1]
parameters used when the schedulable resources are scheduled in a periodic server that runs under a fixed priority scheduling policy.

- `tableEntry`: `OpaqueExpression [0..*]`
parameters used for the particular `SchedulableResource` in a time-triggered, table-based scheduler whose algorithm is expressed in the associated `Scheduler::schedule`.

D.4.9 SchedPolicyKind

This enumeration defines the kinds of scheduling policies defined. It maps to the homonymous concept of the domain view, whose class description is described in Annex F.

Literals

- `EarliestDeadlineFirst`
the scheduler applies the earliest deadline first algorithm.
- `FIFO`
the activations of schedulable resources are served in a first come first served basis.
- `FixedPriority`
the scheduler applies the fixed priority policy.
- `LeastLaxityFirst`
the scheduler applies the least laxity first algorithm to do the scheduling.
- `RoundRobin`
the scheduler shares the processing resource in a round robin way.
- `TimeTableDriven`
the scheduler applies a predefined fixed repetitive schedule.
- `Undef`
the scheduling policy is not specified.
- `Other`
the scheduling policy is none of the included in this enumerated type, but it is specified using a user-defined string.

D.5 MARTE model library for RTOSs

D.5.1 OSEK/VDX OS

D.5.1.1 Overview

OSEK/VDX is the result of an harmonised specification between both a German automotive project named OSEK ("Offene Systeme und deren Schnittstellen für die Elektronik im Kraftfahrzeug" (English: Open Systems and the Corresponding Interfaces for Automotive Electronics)) and a French one named VDX (Vehicle Distributed eXecutive). It aim to provide to the automotive industry a standard for an open-ended architecture for distributed control units in vehicles

The open architecture introduced by OSEK/VDX comprises these three main areas:

- OSEK COM : Communication (data exchange within and between control units)
- OSEK OS : Operating System (real-time execution of ECU software and base for the other OSEK/VDX modules)

- OSEK NM : Network Management (Configuration determination and monitoring)

We mainly focus on OSEK OS 2.2.2 in this section.

The specification of the OSEK operating system is to represent a uniform environment, which supports efficient utilization of resources for automotive control unit application software. The OSEK operating system is a single processor operating system. It describes a static RTOS where all kernel objects are created at compile time.

D.5.2 ARINC-653

D.5.2.1 Overview

The Apex interface, defined in the ARINC 653 standard, provides avionics application software with the set of basic services to access the operating system and other system-specific resources. Its definition relies on the Integrated Modular Avionics (IMA) approach.

A main feature of IMA architectures is that several avionics applications (possibly with different critical levels) can be hosted on a single, shared computer system. A critical issue is to ensure safe allocation of shared computer resources in order to prevent fault propagations from one hosted application to another. This is addressed through a functional partitioning of the applications with respect to available time and memory resources. The allocation unit that results from this decomposition is the partition.

A partition is composed of processes that represent the executive units (an ARINC partition/process is akin to a Unix process/task). When a partition is activated, its owned processes run concurrently to perform the functions associated with the partition. The process scheduling policy is priority pre-emptive.

Each partition is allocated to a processor for a fixed time window within a major time frame maintained by the operating system. Suitable mechanisms and devices are provided for communication and synchronization between processes (e.g. buffer, event, semaphore) and partitions (e.g., ports and channels).

Services of the ARINC 653 Apex interface are provided in the profile.

Annex E: Repetitive Structure Modeling (RSM)

E.1 Overview

Application domains such as signal processing, image processing, or mobile devices, usually require intensive data computations to be performed, possibly in a parallel way, and with the help of several computation units. In the field of embedded systems, we call this kind of systems "intensive computation embedded systems". The purpose of this section is to propose high level modeling constructs that enable to take into account this kind of systems. More precisely, it describes a compact way to express the regularity of such a system's structure or topology. The structures considered are composed of repetitions of structural elements, interconnected via a regular connection pattern. We call this kind of structures "repetitive structures".

The proposed mechanisms are oriented toward two aspects:

- The first aspect concerns the possibility to specify the shape of a repetition specified by a multiplicity, and basically enables to see the collection of potential link ends represented by a multiplicity as a multidimensional array. The purpose is twofold: ease the expression of link topologies, and improve the power of expression of the topology description mechanism.
- The second aspect concerns a way to add topological information on relations expressed between design-time entities in order to specify the topologies of links that will exist between run-time entities in the context of these relations.

These mechanisms can be used in a common way for:

- Hardware execution platform modeling: in order to express all the available parallelism of the platform precisely and in a compact way.
- Application modeling: in order to express the potential parallelism (task and data parallelism) of the application.
- Allocation: Regular temporal and spatial mapping of the application onto the hardware execution platform.

E.2 Domain View

E.2.1 Package overview

The RSM package extends the basic constructs of the MARTE metamodel by providing shaped multiplicities and link topologies. Figure E.1 presents the global structure of this RSM package.

Figure E.1 - Repetitive Structure package

A multiplicity usually enables to determine some instantiation directives about the design time element it is attached to. These directives concern the number of elements that can potentially be instantiated at run time. The multiplicity concept is well known by UML users. In the UML specification, it is defined as an inclusive interval of non negative integers, beginning with a lower bound, and ending with a possibly infinite upper bound. This information is carried by the abstract MultiplicityElement concept (which is the common ancestor to Property, StructuralFeature, ConnectorEnd, ... concepts). It defines the range of allowable cardinalities that a set may assume.

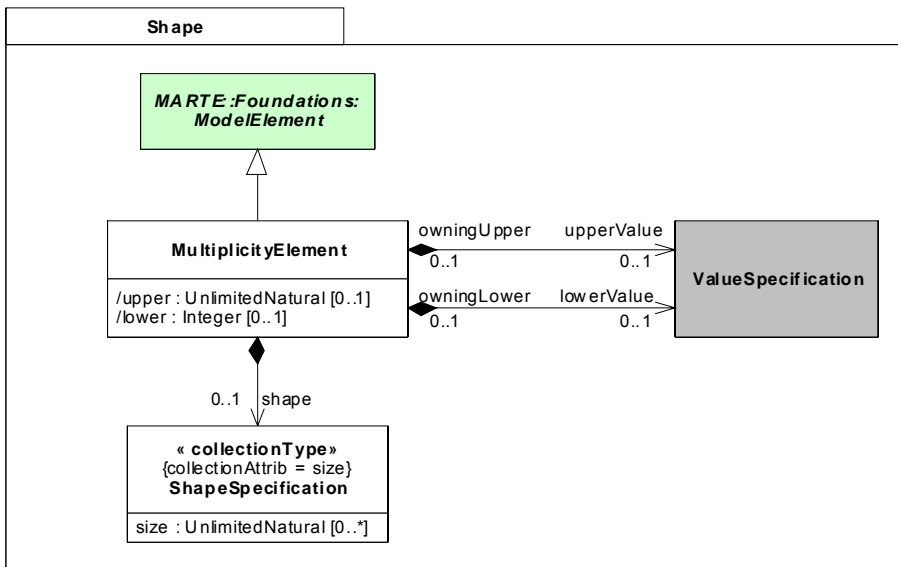

Figure E.2 - Shape modeling concepts

A model element and its associated multiplicity can be seen as a mono dimensional collection of elements. We propose to precise this point of view, and to enable specifying a multidimensional shape for this collection: a model element can be seen as a multidimensional array of model elements via the shape associated to its multiplicity. The concepts used for this shape specification are presented in Figure E.2.

In order to take into account the modeling of link topologies, we introduce the abstract concept of LinkTopology. LinkTopology defines an optional set of information that can be associated to a connector. Basically two use cases are identified. In the first case, links are expressed between potential instances playing the same role. In the second case, links are expressed between potential instances playing different roles. These two use cases lead to the definition of four refinements of the LinkTopology concept: InterRepetition and DefaultLink for the first case and Tiler and Reshape for the second case. Figure E.3 presents these concepts.

Figure E.3 - Link topology modeling concepts

The design idea is to identify sub-arrays, called patterns, of points inside each array (defined by a shape specification), and then to relate the points (i.e. link ends) contained in these patterns. The considered patterns are multidimensional arrays themselves described by a shape. We call tile a pattern when it is considered as a set of points of an array. The considered tiles are sets of regularly spaced points and the tiles themselves are regularly spaced in the array. The description of the regular spacing of the points of a tile is called fitting and the description of the regular spacing of the tiles in the array is called paving. The complete description of the tiling of an array by tiles necessitates the description of the shape of the pattern, the fitting, the paving, an origin and a repetition space. The repetition space gives the number of tiles. It is itself characterized by a shape. The fitting describes the coordinates of the points of the tile in the array relatively to a reference point. The paving describes the set of reference points of the tiles relatively to the origin. So the origin is the point of index $[0, \dots, 0]$ of the tile of index $[0, \dots, 0]$ in the repetition space. The tiling process is described by a Tiler having the attributes: origin, a Vector of Integers, fitting, a Matrix of Integers and paving, a Matrix of Integers. The points of the tile of index r in the repetition space are enumerated as follows: Given the point of index i in the pattern, the coordinates of the corresponding point of in the array is $(\text{origin} + \text{paving} \times r + \text{fitting} \times i) \bmod \text{array_shape}$.

This formula ensures that the points of the tile are regularly spaced because they are built from the reference point of the tile by the linear combination of the column vectors of the fitting matrix; that the reference points of the tiles are regularly spaced because they are built by the linear combination of the column vectors of the paving matrix; and that all points of the tiles are points of the array thanks to the computation modulo the shape of the array. This is inspired by the Array-OL language [1,2,3].

E.2.2 Class description

DefaultLink

The DefaultLink allows specifying a default source or destination for an InterRepetition dependence.

Generalizations

- LinkTopology

Semantics

When some links are not created at run time because of the specification of the InterRepetition topology, a connector with a DefaultLink topology can be specified and connected to one end of the connector having the InterRepetition topology. It defines a link whenever the other one is not present. This allows specifying default values.

Constraints

One connector end must be connected to the same connectable element as a connector having an InterRepetition topology. The connected elements must have the same shape if specified.

InterRepetition

The concerned systems are composed of the repetition of a single element, such as in a grid or cube topology. Each potential instance of this element is connected to other potential instances of the same element. For example, in the case of a cyclic grid, each instance is connected to neighbors located at north, south, east and west. The InterRepetition topology enables to specify the position of every neighbor of every potential instance of a model element with a multidimensional shape.

Generalizations

- LinkTopology

Attributes

- repetitionSpaceDependence: IntegerVector
the repetitionSpaceDependence attribute is a translation vector on the space of the multidimensional array. It identifies the position of a given neighbor.
- modulo: Boolean [0..1] = false
the modulo attribute indicates if the translation is applied modulo the size of the multidimensional array defined by the shape of the repeated element or not. If the modulo attribute is equals to false, the translation is not applied if the target is out of the bounds of the array, and the corresponding links won't be created at run time. This allows to model cyclic grids as well as non cyclic ones.

Semantics

Each potential instance is implicitly associated to one point of the multidimensional array described by the shape associated to the multiplicity of the model element. The coordinates of the neighbor is the addition of the coordinates of the considered point and the repetitionSpaceDependence. The considered point is the source of the topology and the neighbor the destination.

Constraints

If the connector having an InterRepetition topology connects two ports, these two ports must belong to the same part. The repetition space is defined by the multiplicity of that part. If the ports have themselves a multiplicity, the links are established between the sets of instances defined by these multiplicities. The connected elements must have the same shape if specified.

LinkTopology

Each repeated element has a multidimensional shape. Each point of the multidimensional arrays (identified by the multidimensional shapes) corresponds to a potential link end. The mechanism proposed via the LinkTopology concept enables to specify in a compact way all the links existing between potential link ends contained in each of the two arrays. As a consequence, it enables to identify all the links that will exist at run time.

Semantics

This concept is abstract. Its semantics are detailed by its specializations.

MultiplicityElement

The MultiplicityElement defines an interval of number of potential instances. It is extended to support the definition of the shape of the set of the potential instances of the element considered as a multidimensional array of instances.

Attributes

- /upper: UnlimitedNatural [0..1]
upper bound of the multiplicity.
- /lower: Integer [0..1]
lower bound of the multiplicity.
- shape: ShapeSpecification [0..1]
defines the number of dimensions and the size of the dimensions of the multidimensional array of the potential instances of the element.

Constraints

The shape of a collection has a meaning only if the number of elements of this collection is fixed (the upper bound of the multiplicity interval equals its lower bound). Furthermore the isOrdered attribute of the element has to be set to true in order to index the potential instances.

Reshape

This link topology specifies the set of runtime links connecting multidimensional arrays. It defines the tiling of the arrays by an identical pattern. It establishes links between tiles of the arrays.

Generalizations

- LinkTopology

Attributes

- patternShape: ShapeSpecification [1] specifies the shape of the pattern used to tile all the arrays.
- repetitionSpace: ShapeSpecification [1] defines how many tiles there are.
- srcTiler: Tiler [1] specifies the tiling of the source array.
- targetTiler: Tiler [1] specifies the tiling of the target array.

Semantics

A Reshape topology defines a repetition space shape and the shape of the pattern (the same for all link ends). A Tiler has to be associated to each link end. These Tilers describe how the collection of structural features connected to this end is tiled by the tiles.

ShapeSpecification

A ShapeSpecification is the list of the size of the dimensions of an array.

Attributes

- value: UnlimitedNatural[*] {ordered} defines the shape of an array.

Constraints

At most one dimension of a shape can be infinite.

Tiler

A tiler is used in the case when complex topologies are modeled between different potential entities playing different roles. It is based on the tiling of arrays by patterns mechanism.

Generalizations

- LinkTopology

Attributes

- origin: IntegerVector [0..1] the origin is the coordinates of the reference point of the reference tile. When not specified, it defaults to the zero vector.
- fitting: IntegerMatrix [0..1] the fitting matrix defines the regular spacing of the tile points in the array from the reference element of the tile. When not specified, it defaults to the identity matrix.
- paving: IntegerMatrix [1] the paving matrix defines the regular spacing of the reference elements of the tiles from the origin.

Semantics

This is used for example to express the data parallel repetition of an application component. Such a repetition is composed of a repetition component having the repeated component as a part and Tilers connecting the ports of the repetition component to those of the repeated part. The number of repetitions (and the shape of the repetition space) is specified as the multiplicity (and the shape) of the repeated part. As this repetition space is shared by all the Tilers, such a construction establishes links between the tiles of the various ports of the repetition component. Indeed, the tiles of the same repetition index are connected to patterns of the same repeated component part.

E.3 UML Representation

E.3.1 Profile Diagrams

This package stereotyped profile defines the stereotypes and data types needed to model repetitive structures. The possibility to model the shape of multidimensional collection of elements is provided by the shaped stereotype and the specification of the topology of the links between such multidimensional collections is provided by the linkTopology abstract stereotype and its specializations. The distribute stereotype provides a way to specify regular allocations of multidimensional collections of elements to other multidimensional collections of elements, for example a repetition of tasks to a set of processing elements. Figure E.4 presents the Shaped stereotype use to specify the shape of a collection of model elements. Figure E.5 presents the data types needed to specify shapes and tiling parameters. Figure E.6 presents the stereotypes used to specify the various link topologies for composite structures and figure E.7 presents the link topology provided for repetitive allocations, called distributions.

Figure E.4 - Profile diagram for shape modeling

Figure E.5 - Model library defining the data types used by the RSM profile

Figure E.6 - Profile diagram for link topology modeling in composite structures

Figure E.7 - Profile diagram for distribution modeling

E.3.2 Profile Elements Description

DefaultLink

This stereotype maps the DefaultLink domain element defined on page 414.

DefaultLink specifies a default value for an inter-repetition dependence. When such a dependence would refer to a non-existent value, the default value is taken.

Extensions

- Connector (fromUML::InternalStructures).

Generalizations

- LinkTopology.

Attributes

- None

Associations

- None

Constraints

[1] One end of the connector has to be connected to the same port than the end of a connector stereotyped interRepetition.

Distribute

The Distribute stereotype maps the Reshape domain element defined on page 415 to allocations. It adds support of multidimensional distributions to allocations.

A distribute allocation distributes regularly a multidimensional array of elements on another multidimensional array of elements. The repartition of the elements is done exactly in the same way as in the reshape connector (see below).

Extensions

- Abstraction (from UML::Dependencies)

Generalizations

- Allocate (from MARTE::Alloc)
- LinkTopology

Attributes

- kind: AllocationKind [0..1]
inherited from MARTE::Alloc::Allocate.
- nature: AllocationNature [0..1]
inherited from MARTE::Alloc::Allocate.
- patternShape: ShapeSpecification [1]
specifies the shape of the pattern used to tile both from and to arrays.
- repetitionSpace: ShapeSpecification [1]
specifies the repetition space.
- fromTiler: TilerSpecification [1]
specifies the tiling of the from array.
- toTiler: TilerSpecification [1]
specifies the tiling of the to array.

Associations

- None

Constraints

- None

InterRepetition

The InterRepetition stereotype maps the InterRepetition domain element defined on page 414. It specifies an uniform translation in a repetition space.

If the connected ports are directed, then the direction of the translation is from the output port to the input port, else, the translation is considered in both directions, allowing specifying undirected or duplex links.

If the connector is directed, the coordinates of the destination are those of the source plus the repetitionSpaceDependence vector. This addition is considered modulo the shape of the repetition space if the modulo attribute is true, else some links do not exist. In that case, a defaultLink may be specified.

Extensions

- Connector (fromUML::InternalStructures)

Generalizations

- LinkTopology

Attributes

- repetitionSpaceDependence: MARTE::MARTE_Library::MARTE_DataTypes::IntegerVector [1]
specifies the translation vector in the repetition space.
- isModulo: Boolean [0..1]= false
specifies if the translation is taken modulo the shape of the repetition space or not.

Associations

- None

Constraints

- [1] Both ends of the connector must be connected to the same component. This component must have a shape that defines the repetition space.
- [2] The size of the repetitionSpaceDependence has to be the same as that shape as it is a vector in the space defined by that shape.
- [3] Both connector ends must have the same shape.

LinkTopology (abstract)

The LinkTopology abstract stereotype maps the LinkTopology domain element of page 415.

It allows specifying the topology of the potential link instances linking shaped elements. See the tiler stereotype definition below for a full description of the semantics of a reshape connector.

Extensions

- Connector (fromUML::InternalStructures)
- Abstraction (from UML::Dependencies)

Attributes

- None

Associations

- None

Constraints

- None

Reshape

This stereotype maps the Reshape concept of page 415 to assembly connectors. It allows specifying a set of potential connector instances between multidimensional arrays of potential port instances. If the shapes of these arrays of port instances are identical and the connection topology is a direct point-to-point topology, the Reshape stereotype can be omitted. If the shapes are different and no Reshape stereotype is specified, the link topology is indeterminate.

Extensions

- Connector (fromUML::InternalStructures)

Generalizations

- LinkTopology

Attributes

- patternShape: ShapeSpecification [1]
the shape of the pattern used to tile all the arrays.
- repetitionSpace: ShapeSpecification [1]
defines how many tiles there are.

Associations

- None

Constraints

[1] The reshape stereotype can only be applied to assembly connectors.

[2] A tiler stereotype has to be applied to each connector end to specify how each multidimensional array is tiled.

Shaped

The Shaped stereotype maps the MultiplicityElement domain element defined on page 415.

It enables to provide a multidimensional view of a collection of elements. We allow profile users to specify a value only for the shape tag of a shaped MultiplicityElement, without specifying a value for the multiplicity property of the MultiplicityElement.

Extensions

- MultiplicityElement (from UML::Kernel)

Generalizations

- None

Attributes

- shape: ShapeSpecification [1]
allows specifying the shape of a collection (i.e. the number of dimensions and the size of each dimension).

Associations

- None

Constraints

[1] If both a multiplicity and its associated shape are specified, then the product of the elements of the sizes of all the dimensions must be equal to the value of the multiplicity property.

[2] A shaped stereotype can only be applied on an element with a fixed multiplicity, not an interval. If the multiplicity of the element is *, then one of the dimensions of the shape has to be infinite.

Notation

Instead of using the shaped stereotype, the user can write the shape in place of the multiplicity. Whenever a multiplicity is between curly brackets, it has to be understood as a shape specification.

To refer to a specific Element that is part of a multidimensional collection specified by a shape, one can use the ElementName[index] notation where index is the index of this element in the collection. The index is a vector of n naturals where n is the number of dimensions of the shape. The indexes are numbered from 0 to the size of the corresponding dimension minus 1. For example if a part is declared as PE: ProcessingElement [{10,10}] one can refer to the specific PE of index {0,6} by PE[{0,6}].

ShapeSpecification

This data type supports the notation of a shape. It is a vector of unlimited naturals. Each element of the collection is the size of one dimension of a multidimensional array.

Attributes

- size: UnlimitedNatural [0..*] size of each dimension.

Constraints

[1] At most one element of the collection can be infinite.

Notation

As specified in the Value Specification Language (VSL) annex, the shape is a comma separated collection of unlimited naturals between curly brackets, for example: {10, 5, *}.

Tiler

The Tiler stereotype maps the Tiler domain element of page 416.

It expresses how a multidimensional array is tiled by multidimensional tiles. In the case when the tiler stereotype is applied to a delegation connector, it connects an external port with a port of an internal part. The shape of the array is given by the shape of the external port. The shape of the pattern is given by the shape of the port of the internal part. And the shape of the repetition space is given by the shape of this part.

When it is applied to a ConnectorEnd, it belongs to a reshape connector and connects a port of an internal part. The shapes of the repetition space and of the pattern are given by tags of the reshape stereotype. The shape of the array is the concatenation of the shape of the part and the shape of the port. Indeed, the number of potential instances of the port is the product of the multiplicity of the part by the multiplicity of the port. For example the shape of the array of a connector end connected to a port of shape {10, 4} (multiplicity: 40) of a part of shape {25} (multiplicity: 25) is {25, 10, 4} (multiplicity: 1000).

The points of the tile of index r in the repetition space are enumerated as follows: Given the point of index i in the pattern, the coordinates of the corresponding point in the array is (origin + paving x r + fitting x i) mod array_shape.

Extensions

- Connector (from UML::InternalStructures).

- ConnectorEnd (from UML::InternalStructures).

Generalizations

- LinkTopology.

Attributes

- origin: MARTE_Library::MARTE_DataTypes::IntegerVector [0..1]
specifies the origin of the reference tile in the array. If it is absent, the origin is the zero vector of dimension the dimension of the array.
- o fitting: MARTE_Library::MARTE_DataTypes::IntegerMatrix [0..1]
specifies how the pattern is mapped to a tile in the array with respect to a reference element. If it is not specified, the fitting matrix is the identity matrix.
- o paving: MARTE_Library::MARTE_DataTypes::IntegerMatrix [0..1]
specifies how an index in the repetition space is mapped to the reference point of a tile with respect to the reference tile.
- o tiler: TilerSpecification [0..1]
can be use as an alternative to the three previous attributes to specify the origin, fitting and paving using a Tiler object.

Associations

- None.

Constraints

- [1] The tiler stereotype can be applied only to delegation connectors.
- [2] It can be applied to connector ends only if they belong to a connector with the reshape stereotype.
- [3] The tiler attribute can be used only if the origin, fitting and paving attributes are not specified.
- [4] The number of elements of the origin vector, the number of lines of the paving and fitting matrices must be equal to the dimension of the array.
- [5] The number of columns of the paving matrix must be equal to the dimension of the repetition space and the number of columns of the fitting matrix must be equal to the dimension of the pattern.
- [6] Notation
- [7] The vectors of the paving and fitting matrices are column vectors. For example a $\{\{1\},\{0\},\{0\}\}$ matrix has to be interpreted as the $[1\ 0\ 0]$ matrix.

TilerSpecification

This data type supports the notation of a tiler (see the tiler stereotype above for more details on its semantics).

Attributes

- origin: MARTE_Library::MARTE_DataTypes::IntegerVector [0..1]
specifies the origin of the reference tile in the array. If it is absent, the origin is the zero vector of

dimension the dimension of the array.

- fitting: MARTE_Library::MARTE_DataTypes::IntegerMatrix [0..1]
specifies how the pattern is mapped to a tile in the array with respect to a reference element. If it is not specified, the fitting matrix is the identity matrix.
- paving: MARTE_Library::MARTE_DataTypes::IntegerMatrix [1]
specifies how an index in the repetition space is mapped to the reference point of a tile with respect to the reference tile.

Associations

- None

Constraints

- See the Tiler stereotype above

Notation

The notation is as specified in the Value Specification Language (VSL) annex. For example, a tiler specifying a paving of a 2D array by blocks of 5 by 10 elements would be specified as {origin = {0,0}, fitting = {{1,0},{0,1}}, paving = {{5, 0}, {0, 10}}}, or even simply by {paving = {{5, 0}, {0, 10}}}.

E.4 Examples

We propose to illustrate this chapter with the distribution of a repetitive application onto a repetitive hardware architecture.

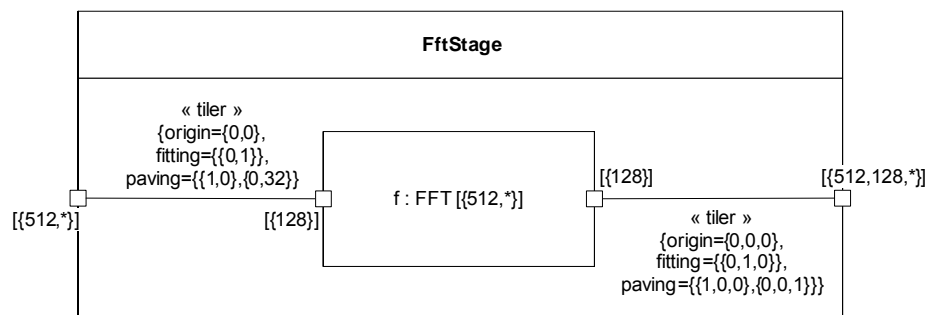

Figure E.8 - 2D repetition of a FFT component

The application, as described by figure E.8 is the first task of a sonar application. It consists of the repetition of a fast Fourier transform on samples recorded by hydrophones distributed around a submarine. This repetition is two-dimensional: a sliding window on time (128 samples every 32 time steps) and a basic repetition on the 512 hydrophones. It consumes a 2D array and produces a 3D array.

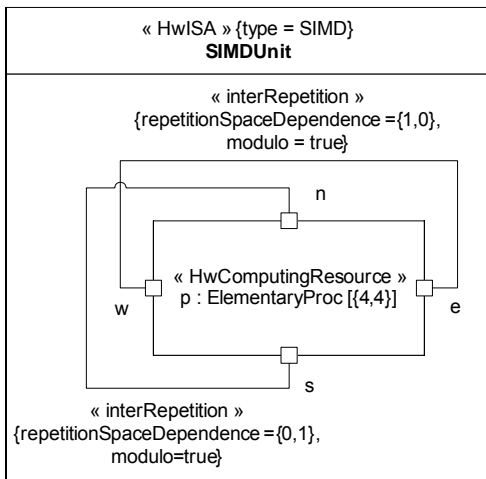

Figure E.9 - 4x4 cyclic grid of processors example

The hardware architecture, as described by figure E.9, is a SIMD unit built as a cyclic grid of 4 by 4 processors. Each elementary processor of the grid is connected to its north, east, south and west neighbors.

Figure E.10 - Bloc distribution example

The allocation, as described by Figure E.10, distributes the computations by blocs of 32 FFTs on the 16 processors of the grid.

Annex F: Domain Class Descriptions

F.1 Core Elements

F.1.1 Action (from Causality::CommonBehavior)

An Action is the fundamental unit of behavior specification.

Generalizations

- Behavior (from Causality::CommonBehavior)

Associations

- None

Attributes

- None

Semantics

An Action is the fundamental unit of behavior specification. An action takes a set of inputs and converts them into a set of outputs, though either or both sets may be empty. Actions are contained in compositeBehaviors, which provide their context. CompositeBehaviors provide constraints among actions to determine when they execute and what inputs they have.

F.1.2 ActionExecution (from Causality::RunTimeContext)

An ActionExecution is a kind of behaviorExecution that corresponds to an instance of an Action, and consequently expresses an atomic piece of behaviorExecution.

Generalizations

- BehaviorExecution (from Causality::RunTimeContext)

Associations

- action: Causality::CommonBehavior::Action [0..1] {subset type}
type of behavior of which the CompBehaviorExecution is an instance.

Attributes

- None

Semantics

An ActionExecution is a kind of behaviorExecution that corresponds to an instance of an Action, and consequently expresses an atomic piece of behaviorExecution. The context in which an actionExecution is performed is obtained by means of the host association inherited from behaviorExecution, which relates the action to its container CompBehaviorExecution, and transitively to the instance of the behaviorClassifier in which it is effectively performed.

F.1.3 AggregationKind (from Foundations)

It is an enumeration type that defines literals used to specify the kind of aggregation between a classifier and its properties.

Literals

- none indicates that there is no aggregation, the property is define by itself
- shared indicates that the property is defined by itself and it may be used by one or more classifiers as part of their respective specifications.
- composite indicates that the property is owned by one classifier as part of its definition.

F.1.4 Behavior (from Causality::CommonBehavior)

A Behavior defines how a system, or an entity defining a part of it, changes over time.

Generalizations

- ModelElement (from Foundations).

Associations

- context: Causality::CommonBehavior::BehaviorClassifier [1]
holds the behaviorClassifier that defines the context in which the behavior is defined.
- Parameter: Causality::CommonBehavior::Parameter [0..*]
indicades the optional set of parameters whose values characterize the behavior..

Attributes

- None

Semantics

A Behavior defines how a system or entity changes over time. From a modeling point of view, this concept defines the behavior of some classifier, specifically, a Behaviored Classifier. A behavior captures the dynamic of its context classifier. It is a specification of how its context classifier as well as the state of the system that is in the scope of the behavior may change over time. A behavior may have Parameters whose values may be used for evaluating a behavior. Two kinds of Behavior may be defined: CompositeBehavior and Action.

F.1.5 BehavioredClassifier (from Causality::CommonBehavior)

A behavioredClassifier is a kind of classifier that represents the context in which behaviors may be specified.

Generalizations

- Classifier (from Foundations)

Associations

- ownedTrigger: Causality::CommonBehavior::Trigger [0..*]
specifies the trigger or triggers that filter events that may affect the execution of behaviors of the classifier.
- ownedBehavior: Causality::CommonBehavior::Behavior [0..*]
specifies the different behaviors that may expose and hold the behavedClassifier.
- mainBehavior: Causality::CommonBehavior::Behavior [0..1] {subset ownedBehavior}
specifies the behavior that is launched after creation and initialization of any instance of the behavedClassifier.

Attributes

- None.

Semantics

A behavedClassifier represents the context in which behaviors may be specified. It exposes concrete behavior specifications to illustrate specific scenarios of interest associated with that classifier, such as the start-up scenario. The particular behavior specification used to represent the behavior that starts executing when instances of that classifier are created and started is called main behavior. For many real-time concurrent systems, this can be for example the behavior that initiates the activity of a thread, which continues until the thread is terminated.

F.1.6 BehaviorExecution (from Causality::RunTimeContext)

A BehaviorExecution is a specification of the execution of a unit of behavior or action within the instances of BehavedClassifiers.

Generalizations

- Instance (from Foundations).

Associations

- host: Causality::RunTimeContext::CompBehaviorExecution [1]
is used to designate the context in which the behavior is being executed.
- cause: Causality::RunTimeContext::EventOccurrence [1]
designates the concrete occurrence of an event that cause the behaviorExecution to take effect.

Attributes

- None.

Semantics

A BehaviorExecution is a specification of the execution of a unit of behavior or action within the instances of BehavedClassifiers. Hence, they are run-time instances of the behavior and action concepts.

Any behavior execution is the direct consequence of the action execution of at least one instance of a classifier. A behavior execution specification describes how the states of these instances change over time. Behavior executions, as such, do not exist by their own, and they do not communicate. If a behavior execution operates on data, that data is obtained from the host instance.

In UML2, there are two kinds of behaviors at run-time, emergent behavior and executing behavior. An executing behavior specification is performed by an instance specification (its host) and is the description of the behavior of this instance. Emergent behavior execution specification results from the interaction of one or more participant instance specifications. MARTE does not highlight this difference on the nature of behaviors. Indeed, it deals only with behavior execution as the general concept to express a behavior instance. Hence, the MARTE BehaviorExecution notion corresponds to the UML2 Behavior Performance concept described in the overview section of its common behavior chapter.

On one hand, a behavior execution specification is thus directly caused by the invocation of a behavioral feature of an instance specification or by its creation. In either case, it is a consequence of the execution of an action by some related classifier instance. A behavior has access to the structural features of its host instance specification.

On the other hand, behavior execution may result from the interaction of various participant instances. If the participating classifier instances are parts of a larger composite classifier instance, a behavior execution can be seen as indirectly describing the behavior of the container instance also. Nevertheless, a behavior execution can result from the executing behaviors of the participant instances. This form of behavior is of interest since the behavior that is to be analyzed and observed at the system level, in order to predict its timing properties, is normally described as an abstract view of the run-time emergent behavior due to the combination of the behavior executions of all its constituent parts.

F.1.7 Classifier (from Foundations)

An abstract concept representing some kind of design-time specification. This concept includes all kinds of descriptors such as classifiers, collaborations, data types, etc.

Generalizations

- ModelElement (from Foundations).

Associations

- instance: Instance [0..*]
indicates the set of run-time instances that are incarnated based on this classifier.
- ownedProperties: Property [0..*]
holds the possible execution behaviors of the instance.

Attributes

- None

Semantics

In the context of the duality classifier-instance, a classifier represents a generic pattern that acts as a design-time specification to which any instance made from it must conform. This concept includes all kinds of descriptors such as classifiers, collaborations, data types, etc. It is generally assumed that every instance element in the domain model may have an implicit or explicit classifier. Properties are used to describe particular aspects of a Classifier.

F.1.8 CompBehaviorExecution (from Causality::RunTimeContext)

A CompBehaviorExecution is a kind of behaviorExecution that corresponds to an instance of a compositeBehavior, and consequently is expressed in terms of other behaviorExecutions.

Generalizations

- BehaviorExecution (from Causality::RunTimeContext).

Associations

- behavior: Causality::CommonBehavior::CompositeBehavior [1] {subset type}
type of behavior of which the CompBehaviorExecution is an instance.
- exAction: Causality::RunTimeContext::BehaviorExecution[0..1]
set of internal behaviorExecutions that define the CompBehaviorExecution. They may be ActionExecutions or other CompBehaviorExecutions.
- host: CoreElements::Foundations::Instance [1]
context in which the behavior is being executed. The associated element corresponds to an instance of a BehavioralClassifier to which the descriptive behavior belongs.
- invoker: CoreElements::Foundations::Instance [0..1]
instance responsible for the invocation of the composite behavior execution.
- participant: CoreElements::Foundations::Instance [1..*]
set of instances that are involved in the execution of the composite behavior.

Attributes

- None

Semantics

A CompBehaviorExecution is a kind of behaviorExecution that corresponds to an instance of a compositeBehavior, and consequently may be expressed in terms of other behaviorExecutions.

The set of participants gives access to the instances that interact to make emerge and are involved in the execution of the composite behavior. This set may include the interacting structural features of its host instance specification.

F.1.9 CompositeBehavior (from Causality::CommonBehavior)

A CompositeBehavior is a kind of Behavior that may contain other Behaviors.

Generalizations

- Behavior (from Causality::CommonBehavior)

Associations

- action: Causality::CommonBehavior::Behavior [0..*]
set of atomic or compositBehaviors used to specify the behavior.

Attributes

- None

Semantics

A CompositeBehavior is a kind of Behavior that may contain other Behaviors, which in turn may be either composite or atomic.

F.1.10 Event (from Causality::CommonBehavior)

An Event is the specification of a kind of change of state that may happen in the modeled system.

Generalizations

- ModelElement (from Foundations)

Associations

- None

Attributes

- None

Semantics

An Event is the specification of a kind of change of state that may happen in the modeled system. Event occurrences are often generated as a result of some action either within the system or in the environment surrounding the system.

F.1.11 EventOccurrence (from Causality::RunTimeContext)

An EventOccurrence is an instance of an Event, representing a potential change of state in the modeled system.

Generalizations

- Instance (from Foundations)

Associations

- event: Causality::CommonBehavior::Event [1] {subset type}
type of event of which the eventOccurrence is an instance.
- effect: Causality::RunTimeContext::BehaviorExecution [0..1]
concrete instance of a behavior whose execution is an effect of the eventOccurrence.

Attributes

- None

Semantics

An EventOccurrence is an instance of an Event. They are used to represent a change of state in the modeled system. Event occurrences are often generated as a result of some action or combination of them, either within the system or in the environment surrounding the system.

F.1.12 Instance (from Foundations)

An abstract concept representing some kind of run-time instance that is created based on one or more type specifications (descriptors). This concept includes all kinds of instances, including objects, data values, etc.

Generalizations

- ModelElement (from Foundations)

Associations

- type: Classifier [0..*]
set of types to which the instance is conformant. These are design-time descriptors that are used to specify all the aspects necessary to run this instance
- exBehavior: RunTimeContext::CompBehaviorExecution [0..*]
holds the possible execution behaviors of the instance.

Attributes

- None

Semantics

In the context of the duality classifier-instance, an instance represents a concrete reification of a classifier. The classifier is referred to as the type of the instance. An instance may have multiple types, which can be used either to represent different viewpoints of the model element or a composition of partial descriptions, including multiple inheritance for example. An instance may expose a number of concrete behaviors at run time; these are expressed by means of a set of composite behavior executions.

F.1.13 InvocationOccurrence (from Causality::Communication)

An InvocationOccurrence is a run time instance that represents the start of a communication in transit between a sender instance and a receiver instance, through the inquiry of an actionExecution.

Generalizations

- EventOccurrence (from Causality::RunTimeContext)

Associations

- effect: Causality::Communication::Request [1..*]
event that will be considered the descriptor of the instance represented by the terminationOccurrence.
- sender: Foundations::Instance [1]
instance that starts the invocation.

- execution: Causality::RunTimeContext::ActionExecution [1]
actionExecution that initiates the invocation.

Attributes

- None

Semantics

An InvocationOccurrence is a run time instance that represents the start of a communication in transit between a sender instance and a receiver instance, through the inquiry of an actionExecution. This actionExecution, representing the invocation of a behavioral feature, is executed by a sender instance resulting in the InvocationOccurrence. The invocation event may represent the sending of a signal or the call to an operation. As a result of the invocationOccurrence a Request is generated. An InvocationOccurrence may result in a number of requests being generated (as in a signal broadcast).

F.1.14 ModelElement (from Foundations)

Abstract root modeling element.

Generalizations

- None

Associations

- ownedElement: ModelElement [0..*]
set of other modeling elements that are part of or define the modelElement in which they are inserted.
- owner: ModelElement [0..1]
modeling element to which this belongs.

Attributes

- name: String [0..1] identifies the element.

Semantics

This abstract class defines a root for most of the concepts defined in this specification. It plays a role similar to the NamedElement concept in the UML metamodel. The ownedElement - owner association is used to bring it containing capabilities, which can be used to defined composite model elements.

F.1.15 Parameter (from Causality::CommonBehavior)

It is a typed element that may be owned by a behavior.

Generalizations

- ModelElement (from Foundations)

Associations

- type: Classifier [0..1] type of the parameter by means of a classifier.

Attributes

- None

Semantics

A parameter is a typed element that may be owned by a behavior. Values assigned to parameters are to be consistent with its type, and are used to characterize the different scenarios and variations of a behavior.

F.1.16 Property (from Foundations)

It is a typed element that may be owned by a classifier.

Generalizations

- ModelElement (from Foundations)

Associations

- type: Classifier [0..1] type of the property by means of a classifier.

Attributes

- aggregation: AggregationKind [1] = none kind of aggregation used to include the property in a classifier.

Semantics

As the UML homonymous concept a property is a typed element that may be owned by a classifier. It has a multiplicity in terms of upper and lower bounds, an aggregation kind and a type. It is used to describe particular aspects of a Classifier, by giving to it concrete values at instantiation time. This concept is consistent with the UML::Classes::Kernel::Property element of the UML2 metamodel.

F.1.17 ReceiveOccurrence (from Causality::Communication)

A ReceiveOccurrence is a run time instance that represents the reception of a communication in transit between a sender instance and a receiver instance.

Generalizations

- EventOccurrence (from Causality::RunTimeContext)

Associations

- cause: Causality::Communication::InvocationOccurrence [1] received request.
- receiver: Foundations::Instance [1] instance that receives the request.

Attributes

- None

Semantics

A ReceiveOccurrence is a run time instance that represents the reception of a communication in transit between a sender instance and a receiver instance. Once the generated request arrives at the receiver instances, a ReceiveOccurrence occurs, which according to the triggers expected may subsequently launch the behaviors of the receiver instance or of any of its internal instances. Like in the Common Behaviors Domain Model of UML, two kinds of requests are determined according to the kind of invocation occurrence that caused it: the sending of a signal, and the invocation of an operation. The former is used to trigger a reaction in the receiver in an asynchronous way without a reply. The latter applies an operation to an instance, which may be synchronous or asynchronous and may require a reply from the receiver to the sender.

F.1.18 Request (from Causality::Communication)

A Request is an instance of a communication in transit between a calling instance and a called one.

Generalizations

- Instance (from Foundations)

Associations

- effect: Causality::Communication::ReceiveOccurrence [1]
receiveOccurrence that will handle the reception of the request.
- cause: Causality::Communication::InvocationOccurrence [1]
invocationOccurrence that originates the request.
- sender: Foundations::Instance [1]
instance that starts the invocation.
- receiver: Foundations::Instance [1]
instance that receives the request.

Attributes

- None

Semantics

A Request, which fully corresponds to the Request concept of UML 2, is an instance of a communication in transit between a calling instance and a called one. In fact, a request is an instance capturing the data that was passed to the action causing the invocation event (the arguments that must match the parameters of the invoked behavioral feature); information about the nature of the request (i.e., the behavioral feature that was invoked); the identities of the sender and receiver instances; as well as sufficient information about the behavior execution to enable the return of a reply from the invoked behavior, where appropriate. Eventually the request may include additional information, like a time stamp.

Each request is targeted at exactly one receiver instance and caused by exactly one sending instance, but an occurrence of an invocation event may result in a number of requests being generated (as in a signal broadcast). The receiver may be the same instance that is the sender, it may be local (i.e., an instance held inside the currently executing instance, or the currently executing instance itself, or the instance owning the currently executing instance), or it may be remote. The manner of transmitting the request, the amount of time required to transmit it, the order in which the transmissions reach their receiver instances, and the path for reaching the receiver instances are to be defined and annotated by using any of the different communication mechanisms available, like rendezvous, message queuing, interrupts, etc.

F.1.19 StartEvent (from Causality::Invocation)

A StartEvent represents the start of a Behavior.

Generalizations

- Event (from Causality::CommonBehavior)

Associations

- behavior: Causality::CommonBehavior::BehaviorExecution [1]
behavior whose start is represented by the StartEvent.

Attributes

- None

Semantics

A StartEvent represents the start of a Behavior. The event is tied to the start of the associated behavior.

F.1.20 StartOccurrence (from Causality::Invocation)

A StartOccurrence represents the start of a BehaviorExecution.

Generalizations

- EventOccurrence (from Causality::RunTimeContext).

Associations

- startEvent: Causality::Invocation::StartEvent [1] {subset event}
event that will be considered the descriptor of the instance represented by the startOccurrence.
- execution: Causality::RunTimeContext::BehaviorExecution [1]
behaviorExecution whose start is represented by the startOccurrence.

Attributes

- None

Semantics

A StartOccurrence represents the start of a BehaviorExecution. The occurrence is tied to the start of the associated behaviorExecution.

F.1.21 TerminationEvent (from Causality::Invocation)

A TerminationEvent represents the finalization of a Behavior.

Generalizations

- Event (from Causality::CommonBehavior)

Associations

- behavior: Causality::CommonBehavior::BehaviorExecution [1]
behavior whose termination is represented by the terminationEvent.

Attributes

- None

Semantics

A TerminationEvent represents the finalization of a Behavior. The event is tied to the finalization of the associated behavior.

A TerminationOccurrence represents the finalization of a BehaviorExecution.

Generalizations

- EventOccurrence (from Causality::RunTimeContext)

Associations

- endEvent: Causality::Invocation::TerminationEvent [1] {subset event}
event that will be considered the descriptor of the instance represented by the terminationOccurrence.
- execution: Causality::RunTimeContext::BehaviorExecution [1]
behaviorExecution whose termination is represented by the terminationOccurrence.

Attributes

- None

Semantics

A TerminationOccurrence represents the finalization of a BehaviorExecution. The occurrence is tied to the finalization of the associated behaviorExecution.

F.1.22 TerminationOccurrence (from Causality::Invocation)

A TerminationOccurrence represents the finalization of a BehaviorExecution.

Generalizations

- EventOccurrence (from Causality::RunTimeContext)

Associations

- endEvent: Causality::Invocation::TerminationEvent [1] {subset event}
event that will be considered the descriptor of the instance represented by the terminationOccurrence.
- execution: Causality::RunTimeContext::BehaviorExecution [1]
behaviorExecution whose termination is represented by the terminationOccurrence.

Attributes

- None

Semantics

A TerminationOccurrence represents the finalization of a BehaviorExecution. The occurrence is tied to the finalization of the associated behaviorExecution.

F.1.23 Trigger (from Causality::CommonBehavior)

A Trigger specifies the event and conditions that may trigger a behavior execution.

Generalizations

- ModelElement (from Foundations)

Associations

- event: Causality::CommonBehavior::Event [1]
event that will be considered to start the associated BehavedClassifier.

Attributes

- None

Semantics

A Trigger specifies the event and conditions that may trigger a behavior execution. It handles as well any necessary constraints on the event to filter out event occurrences not of interest. Indeed, a Trigger is the concept that relates an Event to a Behavior that may affect instances of the behavioral classifier. Triggers specify what can cause execution of behaviors (e.g., the execution of the effect activity of a transition in a state machine).

F.2 NFP

F.2.1 AbstractNFP (abstract, from NFP_Nature)

AbstractNFP defines the abstract concept of Non-Functional Property (NFP) as quantitative or qualitative information.

Semantics

A non-functional property (NFP) is also called extra-functional property or even quality of service depending of the application domain. It describes how a computing system behaves.

F.2.2 AnnotatedElement (abstract, from NFP_Annotation)

An annotated model element is a model element with additional annotations implemented by standard modeling mechanisms (for instance, the UML profile extension mechanism). An annotated model element describes certain of its non-functional aspects by means of NFP annotations.

Generalizations

- ModelElement (from CoreElements::Foundations).

Associations

- owner: AnnotatedModel [1] modeling context of the annotated element.
- nfpValue : MARTE::VSL::ValueSpecification [*] set of value annotations associated with non-functional properties.
- nfpDeclaration: NFP [*] set of NFP declarations owned by the annotated element.

Semantics

Annotated Elements are model elements extended by standard modeling mechanisms. For example, some typical performance analysis-related annotated elements are: Step (a unit of execution), Scenario (a sequence of Steps), Resource (an entity that offers one or more services), Service (offered by a Resource or by a component of some kind). An annotated element describes certain of its non-functional aspects by means of NFP value annotations.

F.2.3 AnnotatedModel (abstract, from NFP_Annotation)

An annotated model is a model with additional semantic expressing concepts from a given modeling concern or domain viewpoint. An annotated model contains annotated model elements.

Associations

- owns: AnnotatedElement [*] annotated elements owned by the model.
- annotationConcern: ModelingConcern [1..*] modeling concerns for which the model is created.
- ownedRule: NFP_Constraint [*] set of Constraints owned by this model.

Semantics

An annotated model is a model with additional semantic required for a given modeling concern or domain. An annotated model may contain annotated model elements.

F.2.4 BasicQuantity (abstract, from NFP_Nature)

Basic quantities are primitive quantities. Many other quantities can be derived out of the combination of the basic quantities (see Derived Quantity). Example of basic quantities are length, mass, time, current, temperature and luminous intensity. The units of measure for the basic quantities are organized in systems of measures, such as the universally accepted Système International (SI) or International System of Units.

Generalizations

- Quantity (from NFP_Nature).

Semantics

Basic quantities are primitive quantities. They may be used to obtain derived quantities. Example of basic quantities are length, mass, time, current, temperature and luminous intensity. The units of measure for the basic quantities are organized in systems of measures, such as the universally accepted *Système International (SI)* or *International System of Units*.

F.2.5 ConstraintKind

Kind of constraints qualifies NFP constraints by either required, offered, or contract nature.

Literals

- required
- offered
- contract

F.2.6 DerivedQuantity (abstract, from NFP_Nature)

Derived Quantities (e.g., area, volume, force, frequency) may be obtained from the basic quantities by known formulas.

Generalizations

- Quantity (from NFP_Nature) on page 51.

Associations

- None

Semantics

Derived physical quantities (which are the majority of quantities) are defined by a mathematical expression involving either the fundamental (basic) quantities or other derived quantities.

F.2.7 DirectionKind

The direction kind (i.e., increasing or decreasing) defines the type of the quality order relation in the allowed value domain of NFPs.

Literals

- increasing
- decreasing

F.2.8 Measure (abstract, from NFP_Nature)

A Measure is a (statistical) function (e.g, mean, max, min, mean) characterizing the set of sample realizations.

Associations

- `physicalQuantity`: Quantity [1] physical magnitude of a measure.
- `measurementUnit`: Unit [0..1] measurement unit associated with the physical quantity used for expressing a measure.
- `domain`: SampleRealization [1..*] set of sample realizations used for obtaining a measure.

Semantics

A Measure is a (statistical) function (e.g. mean, max, min, median, variance, standard deviation, histogram, etc.) characterizing a set of samples realizations. Measures may be computed either directly by applying one function to the set of realization values, or by using theoretical functions of the probability distribution given for the respective quantitative NFP.

F.2.9 ModelingConcern (from NFP_Annotation)

Concerns are those interests which pertain to the system's development, its operation or any other aspects that are critical or otherwise important to one or more stakeholders at a given point of the development process.

Associations

- `relevantNfp`: NFP [*]
due to the abstraction involved in the construction of a model, only some NFPs are relevant to a certain Modeling Concern. In other words, a given modeling concern uses a set of NFPs which establishes the ontology of the domain.

Attributes

- `description` : String [0..1]
name of the concern that is expressed by a model. (This name may refer to a profile definition.)

Semantics

Concerns are those interests which pertain to the system's development, its operation or any other aspects that are critical or otherwise important to one or more stakeholders at a given point of the development process.

F.2.10 NFP (from NFP_Declaration)

Non-Functional Properties (NFPs) declares an attribute of one or more instances in terms of a named relationship to a value or values.

Associations

- `type` : NFP_Type [1]
NFP_Type that constraints the values of the NFP.
- `defaultValue` : MARTE::VSL::ValueSpecification [0..1]
NFP value specification that is evaluated to give a default value for the NFP when an instance of the owning Annotated Element is created.

Attributes

- None

Semantics

Functional properties, which are primarily concerned with the purpose of an application (i.e., what it does); and non-functional properties (NFPs), which are more concerned with its fitness for purpose (i.e., how well it does it or it has to do it). NFPs are specified by the designer in the models and attached to different model elements.

F.2.11 NFP_Constraint (from NFP_Annotation)

NFP Constraints are conditions or restrictions to modelled elements providing the ability to define if these are of "required", "offered", or "contract" nature.

Associations

- constrainedElement: AnnotatedElement [*]
set of Annotated Elements referenced by this NFP Constraint.
- context: AnnotatedModel [0..1]
Namespace that is the context for evaluating this constraint.
- specification: ValueSpecification [1]
condition that must be true when evaluated in order for the constraint to be satisfied.

Attributes

- kind: ConstraintKind [0..1]
tagged definition qualifies NFP constraints by either required, offered, or contract nature.

Semantics

NFP Constraints are conditions or restrictions to modelled elements. Specifically, NFP constraints support textual expressions to specify assertions regarding performance, scheduling, and other embedded systems' features, and their relationship to other features by means of variables, mathematical, logical, and time expressions.

F.2.12 NFP_Type (abstract, from NFP_Declaration)

A NFP type is a type whose instances are identified only by NFP value specifications. A NFP Type contains specific attributes to support the modeling of NFP tuple types.

Generalizations

- TupleType (from VSL::DataTypes) on page 568.

Associations

- allowedUnit: Unit [*]
set of measure units valid for the NFP Types.
- defaultUnit: Unit [0..1]
measure unit valid as a default value for all the value specifications of this NFP type.

- valueAttribute: UML::Classes::Kernel::Property [1]
tuple attribute representing the resulting value after evaluating the expression of the data type.
- exprAttribute: UML::Classes::Kernel::Property [0..1]
tuple attribute representing an expression. MARTE uses the VSL language to define expressions.
- unitAttribute: UML::Classes::Kernel::Property [0..1]
tuple attribute representing a measurement unit of a data type for physical properties.
- qualifierAttributed: UML::Classes::Kernel::Property [*]
attributes offering completeness to the value attribute.

Semantics

A NFP Type constrains the values represented by a NFP. If a NFP type has attributes, then instances of that NFP type will contain attribute values matching the attributes.

F.2.13 QualitativeNFP (abstract, from NFP_Nature)

Qualitative NFP refer to inherent or distinctive characteristics that may not be measured directly. More specifically, a qualitative NFP takes a value from a list of allowed values, where each value identifies a possible alternative.

Generalizations

- AbstractNFP (from NFP_Nature)

Associations

- parameter: AbstractNFP [*] set of parameters of a qualitative NFP.

Semantics

A Qualitative NFP is a non-functional property that is not a quantitative NFP. Especially, a qualitative NFP is not physically measurable. In general, a qualitative NFP is denoted by a label representing a high-level of abstraction characterization that is meaningful to the analyst and the analysis tools.

F.2.14 QuantitativeNFP (abstract, from NFP_Nature)

Quantitative NFP are measurable, countable, or comparable properties. A given quantitative NFP may be characterized by a set of Sample Realizations and Measures.

Generalizations

- AbstractNFP (from NFP_Nature)

Associations

- measure: Measure [0..*]
set of measures defining a quantitative NFP.
- realizationValues: SampleRealization [0..*]
set of sample values used to define a quantitative NFP.

Semantics

A Quantitative NFP is a non-functional property that is measurable, countable, or comparable, and can be represented by an amount which is a numerical value.

F.2.15 Quantity (abstract, from NFP_Nature)

A physical property characterizing some aspect of nature that can be measured.

Attributes

- allowedUnits: Unit [*] set of measure units valid for the physical quantity.

Semantics

A physical quantity is either a quantity within physics that can be measured (e.g. mass, volume), or the result of a measurement. Physical quantities are usually associated with a set of valid measure units.

F.2.16 SampleRealization (abstract, from NFP_Nature)

A Sample Realization represents a set of values that occur for the quantitative NFP under consideration at run-time.

Associations

- function: Measure [0..*] set of functions applied to a set of values to obtain separated measures.

Semantics

Sample Realizations represent a set of values that occur for the Quantitative NFP under consideration at run-time (for instance, measurements collected from a real system or a simulation experiment). A Quantitative NFP may be sampled once or repeated times over an extended run. In a cyclic deterministic system, in which each execution cycle has the same values, a single sample is sufficient to characterize completely the Quantitative NFP.

F.2.17 StatisticalQualifierKind

A statistical qualifier kind lists the type of "statistical" measure of a given property

Literals

- max
- min
- mean
- range
- percentile
- distribution
- deterministic

F.2.18 Unit (from NFP_Nature)

A unit defines a quantity in terms of which the magnitudes of other quantities that have the same dimension can be stated.

Associations

- baseUnit: Unit [0..1]
base unit by which a measurement unit is derived. Basic units of the International System of Measures do not define this attribute.

Attributes

- convFactor: Real [0..1]
parameter that allows referencing measurement units to other base units by a numerical factor.
- convOffset: Real [0..1]
parameter that allows referencing measurement units to other base units by applying an offset value to them.

Semantics

A unit defines a quantity in terms of which the magnitudes of other quantities that have the same dimension can be stated. A unit often relies on precise and reproducible ways to measure the unit. For example, a unit of length such as meter may be specified as a multiple of a particular wavelength of light. A unit may also specify less stable or precise ways to express some value, such as a cost expressed in some currency, or a severity rating measured by a numerical scale.

F.3 Time

F.3.1 ChronometricClock (from TimeAccesses::ChronometricClocks)

A chronometric clock is a clock bound to physical time. Some properties are specific to a clock; others are related to a pair of clocks.

Generalizations

- Clock (from TimeAccesses::Clocks)

Associations

- referenceClock: ChronometricClock [0..1] references a chronometric clock against which this clock can be compared.

Attributes

Characteristics inherent in a chronometric clock:

- /rate: Real [0..1] the reciprocal of the resolution. This is derived.
- stability: Real [0..1] the derivative of the clock rate either against time or against a physical parameter.
- standard: TimeStandardKind[0..1] the time standard on which this chronometric clock relies.

Pair-wise characteristics of chronometric clocks:

- drift: Real [0..1] the first derivative of the skew
- offset: DurationValue [0..1] the difference between two clocks at a particular instant in time.
- skew: Real [0..1] the rate of change of the offset (i.e., its first derivative) at a particular instant in time.

Semantics

A chronometric clock is a clock bound to physical time. It can yield a "time reading". Clock characteristics reflect imperfections of clocks to accurately follow physical time evolutions.

F.3.2 Clock (from TimeAccesses::Clocks)

A clock provides access to time.

Generalizations

- AnnotatedElement (from NFPs::NFP_Annotation)

Associations

- acceptedUnits: NFPs::NFP_Nature::Unit [1..*]
set of units accepted by this clock.
- clockTick: CoreElements::Causality::CommonBehavior::Event [0..1]
references an event owned by the clock. This event occurs whenever the clock changes its current time.
- defaultUnit: NFPs::NFP_Nature::Unit [1]
unit attached to the currentTime value of this clock. Subsets Clock::acceptedUnits.
- timeBase: DiscreteTimeBase [1]
the discrete time base, whose instants correspond to the clock's ticks.

Attributes

- currentTime: Real [1]
references the current instant value.
- maximalValue: Real [0..1]
if defined, the clock rolls over when it gets at maximalValue.
- nature: TimeNatureKind [1]
specifies whether time values are from a discrete or a dense set.
- resolution: Real [1] = 1.0
the duration value expressed in defaultUnit between two consecutive ticks of this clock.

Semantics

A clock provides access to a discrete time base, and possibly to a dense time base, but through a discrete time base. The instants of this time base correspond to "ticks" of the clock. A clock associates time values with instants of the time base. These values may be from a discrete or a dense set of values.

A Clock accepts units (acceptedUnits property). Unit is defined in the NFP_Nature package. One of these accepted units is the defaultUnit, which is attached to the currentTime value.

Clock is an abstract class.

F.3.3 ClockConstraint (from TimeRelatedEntities::ClockConstraints)

A clock constraint constrains two or more clocks.

- Generalizations
- NfpConstraint (from NFPs::NFP_Annotation)

Associations

- constrainedClocks: Clock[2..*]
references the clocks on which the constraint applies. Subsets
NFPs::NFP_Annotation::NfpConstraint::constrainedElement.
- specification: ClockConstraintSpecification[1]
references the specification of the clock constraint. Redefines
NFPs::NFP_Annotation::NfpConstraint::specification.

Attributes

- None

Semantics

A clock constraint constrains two or more clocks. The specification of the constraint is expressed by a clock expression.

F.3.4 ClockConstraintSpecification (from TimeRelatedEntities::ClockConstraints)

A value specification that specifies constraints imposed to clocks.

Generalizations

- None

Associations

- None

Attributes

- None

Semantics

A value specification that specifies constraints imposed to clocks. An example of clock constraint specification is that two clocks are harmonic with one twice faster than the other. A dedicated language (CCSL: Clock Constraint Specification Language) is proposed with MARTE (Annex C).

F.3.5 CoincidenceRelation (from MultipleTimeModels)

A coincidence relation relates junction instants which are coincident.

Generalizations

- TimeInstantRelation (from MultipleTimeModels)

Associations

- coincidentJIs: JunctionInstant [2..*]
references a set of coincident junction instants. Subsets TimeInstantRelation::relatedJIs.

Attributes

- None

Semantics

A coincidence relation relates junction instants which are coincident. These instants are owned by distinct time bases.

Constraints

[8] All coincident junction instants in a coincidence relation are owned by distinct time bases.

coincidentJIs->forall(i,j | i<>j implies i.tb <> j.tb)

F.3.6 Delay (from TimeRelatedEntities::TimedProcessingModels::TimedProcessings)

Delay is a special kind of TimedAction that represents a null action lasting for a given duration.

Generalizations

- TimedAction (from TimeRelatedEntities::TimedProcessingModels::TimedProcessings)

Associations

- None

Attributes

- None

Semantics

Delay is a special kind of TimedAction that represents a null action lasting for a given duration.

F.3.7 DiscreteTimeBase (from BasicTimeModels)

A DiscreteTimeBase represents an ordered discrete set of instants.

Generalizations

- TimeBase (from BasicTimeModels)

Associations

- coveringTB: TimeBase[0..1]

if present, it references the dense time base of which this discrete time base is a discretization.

Attributes

- None

Semantics

A discrete time base represents an ordered set of discrete instants. A discrete time base can be referred to by a clock, and thus allows access to the time structure.

Constraints

[1] The nature of a discrete time base is discrete

self.nature = TimeNatureKind::discrete

[2] All instants owned by a discrete time base are junction instants

self.instants->forAll(j | j.oclIsTypeOf(JunctionInstant))

F.3.8 DurationIntervalValue (from TimeAccesses::DurationValues)

A duration interval value is defined by a pair of duration values.

Generalizations

- None

Associations

- maxD: DurationValue [1]
references the duration value which stands for the maximal value of this duration interval value.
- minD: DurationValue [1]
references the duration value which stands for the minimal value of this duration interval value.

Attributes

- isMinDOpen: Boolean [1] = false
specifies whether the minimal instant value is in this duration interval value or not. When this attribute is true, then the minimal duration value is not in the interval. The default value is false.
- isMaxDOpen: Boolean [1] = false
specifies whether the maximal duration value is in the interval or not. When this attribute is true, then the maximal duration value is not in the interval. The default value is false.

Semantics

A duration interval value is defined by a pair of duration values. By default a duration interval value is closed (including the bound values). When used in a time value specification, a duration interval value designates any duration value of the interval (including or not the bound values according to the isMinDOpen and isMaxDOpen attribute values).

Constraints

[1] minD and maxD duration values of this duration interval value have the same onClock clock.

minD.onClock = maxD.onClock

F.3.9 DurationPredicate (from TimeRelatedEntities::TimedConstraints)

DurationPredicate is a predicate on a duration expression.

Generalizations

- DurationExpression (from VSL::TimeExpressions)

Associations

- observation: TimedObservation [1..*] references timed observations used in the expression.

Attributes

- None

Semantics

DurationPredicate is a predicate on a duration expression. Note that the expression may involve two TimedInstantObservation, say t1 and t2, a TimedDurationObservation, say d, and use "(t1-t2)+d", which effectively denotes a duration.

F.3.10 DurationValue (from TimeAccesses::DurationValues)

A duration value is a time value that characterizes a time span measured on its onClock clock.

Generalizations

- TimeValue (from TimeAccesses::TimeValues)

Associations

- intervalValue: TimeIntervalValue [1]references the time interval value for which the duration value is determined.

Attributes

- None

Semantics

A duration value is a time value that characterizes the time span of a time interval measured on its onClock clock. In the simple case when the clock has no defined maximalValue, the DurationValue of a TimeIntervalValue is defined by the difference between the max and min instant values of this time interval value. When the maximalValue property is defined, the DurationValue is defined as the difference modulo maximalValue between the max and min instant values of this time interval value.

Constraints

[1] The intervalValue is on the same clock as the duration value

self.onClock = intervalValue.min.onClock

-- note that the same holds for intervalValue.max (constraint [1], page 462)

F.3.11 EventKind (from TimeRelatedEntities::TimedElements::TimeObservations)

EventKind is an enumeration type that defines literals used to specify the kind of event used in a timed observation.

Literals

- start indicates that the typed elements is the start event of a behavior execution.
- finish indicates that the typed elements is the finish event of a behavior execution.
- send indicates that the typed elements is the sending event of a request.
- receive indicates that the typed elements is the receipt event of a request.
- consume indicates that the typed elements is the start event of the processing of a received request by the receiver.

F.3.12 Instant (from BasicTimeModels)

An instant represents an element of a time base (a point in time).

Generalizations

- None

Associations

- tb: TimeBase [1] references the owning time base.

Attributes

- date:Real [0..1] specifies a value attached to this instant.

Semantics

An instant represents a point in time. It is owned by a time base in which it occupies a unique position with respect to the other instants of this time base.

F.3.13 InstantPredicate (from TimeRelatedEntities::TimedConstraints)

InstantPredicate is a predicate on an instant expression.

Generalizations

- InstantExpression (from VSL::TimeExpressions)

Associations

- observation: TimedObservation [1..*] references timed observations used in the expression.

Attributes

- None

Semantics

InstantPredicate is a predicate on an instant expression. Note that the expression may involve a TimedInstantObservation, say t, a TimedDurationObservation, say d, and use "t+d", which effectively denotes an instant.

F.3.14 InstantValue (from TimeAccesses::TimeValues)

An instant value is a time value that denotes instants of the time base associated with its onClock clock.

Generalizations

- TimeValue (from TimeAccesses::TimeValues)

Associations

- denotedInstant: JunctionInstant [0..*]
references junction instants denoted by this instant value. These instants are owned by the time base associated with the onClock clock of this instant value.

Attributes

- None

Semantics

An instant value is a time value that denotes junction instants of the time base associated with its onClock clock. When the onClock clock has a maximal value, due to clock roll-over, an instant value may denote many instants.

Constraints

[1] All junction instants denoted by this instant value are owned by the timeBase time base of the onClock clock of this time value.

denotedInstant->forAll(j | j.tb = self.onClock.timeBase)

F.3.15 JunctionInstant (from BasicTimeModels)

A junction instant represents a point in time. All instants owned by a discrete time base are junction instants. Some instants of a dense time base may be junction instants

Generalizations

- Instant (from BasicTimeModels)

Associations

- None

Attributes

- None

Semantics

A junction instant represents a point in time. A junction instant can be referred to by a time instant relation.

F.3.16 LogicalClock (from TimeAccesses::Clocks)

A logical clock provides access to a logical time, that is, a model of time in which only the ordering of instants is meaningful. There is no implicit reference to the physical time.

Generalizations

- Clock (from TimeAccesses::Clocks)

Associations

- definingEvent: CoreElements::Causality::CommonBehavior::Event [0..1]
references an event whose occurrences define the logical instants of this clock: this logical clock ticks at each occurrence of the definingEvent.

Attributes

- None

Semantics

A logical clock provides access to a logical time, that is, a model of time in which only the ordering of instants is meaningful. There is no implicit reference to the physical time. Logical clocks are often used in conjunction with a time structure model accessible through its timeBase property. A logical clock can also be defined by any event (its definingEvent). In this case, the logical clock ticks at each occurrence of this event.

F.3.17 MultipleTimeBase (from MultipleTimeModels)

A multiple time base represents a multiform time. It consists of a set of time bases.

Generalizations

- None

Associations

- nestedMTBs: MultipleTimeBase [0..*]
set of multiple time bases owned by this multiple time base.
- ownedTBs: TimeBase [0..*]
set of time bases owned by this multiple time base.

- **parentMTB:** MultipleTimeBase [0..1]
MultipleTimeBases can be nested. If the parentMTB property is defined, it references the unique owning MultipleTimeBase.
- **tsRelations:** TimeStructureRelation [0..*]
set of possible relationships that constraint the time bases owned directly or indirectly by this time base.

Attributes

- None

Semantics

A multiple time base represents a multiform time structure. It owns one or many time bases. Multiple time bases can be nested. The set of instants indirectly owned by the top multiple time base is partially ordered. This partial ordering of instants characterizes the time structure.

Additional operations

[1] The operation `allIncludedTimeBases` results in the set of all the time bases that are directly or indirectly member of a multiple time base.

MultipleTimeBase::allIncludedTimeBases (): Set(TimeBase);

allIncludedTimeBases = ownedTBs->union(ownedTBs.allIncludedTimeBases ())

[2] The operation `allMemberJunctionInstants` results in the set of all the junction instants owned by a time bases that ar directly or indirectly member of a multiple time base.

MultipleTimeBase::allMemberJunctionInstants (): Set(JunctionInstant);

allMemberJunctionInstants = self.allIncludedTimeBases().instants

Constraints

[1] All related time bases in a time base relation are directly or indirectly contained in this multiple time base.

self.allIncludedTimesBases()->includesAll(self.relatedTBs)

[2] All related junction instants in a time instant relation are owned by a time base directly or indirectly contained in this multiple time base.

self.allMemberJunctionInstants()->includesAll(self.relatedJIs)

F.3.18 PhysicalTime (from TimeAccesses::ChronometricClocks)

Physical time is an abstract concept in MARTE. Physical time does not directly participate in the model.

Semantics

Physical time is considered as a continuous and unbounded progression of physical instants. Physical time is assumed to progress monotonically (with respect to any particular observer) and only in the forward direction. For a given observer, it can be modeled as a dense time base.

F.3.19 PrecedenceRelation (from MultipleTimeModels)

A precedence relation relates two junction instants, from distinct time bases, which are temporally ordered.

Generalizations

- TimeInstantRelation (from MultipleTimeModels)

Associations

- after: JunctionInstant [1]
references a junction instant which is (temporally) after the before junction instant. Subsets TimeInstantRelation::relatedJIs.
- before: JunctionInstant [1]
references a junction instant which is (temporally) before the after junction instant. Subsets TimeInstantRelation::relatedJIs.

Attributes

- None

Semantics

A precedence relation relates two junction instants, from distinct time bases, which are temporally ordered: the before junction instant precedes the after junction instant.

Constraints

[3] The before and the after junction instants of a precedence relation are owned by distinct time bases.

after.tb <> before.tb

F.3.20 SimultaneousOccurrenceSet (from TimeRelatedEntities::TimedEvent Models::TimedEventOccurrences)

SimultaneousOccurrenceSet represents a set of occurrences considered as a whole.

Generalizations

- EventOccurrence (from CoreElements::Causality::RunTimeContext)

Associations

- occSet: CoreElements::Causality::RunTimeContext::EventOccurrence[0..*]
set of event occurrences considered as a whole.

Attributes

- None

Semantics

SimultaneousOccurrenceSet represents a set of occurrences considered as a whole. Since a SimultaneousOccurrenceSet is also an EventOccurrence, it may cause changes in the system.

F.3.21 TimeBase (from BasicTimeModels and MultipleTimeModels)

A TimeBase represents an ordered set of instants.

Generalizations

- None

Associations

- instants: Instant [0..*] {ordered}
references the ordered set of instants owned by this time base.
- currentInstant: Instant [1]
it references the current instant of this time base. Subsets TimeBase::instants.
(from MultipleTimeModels)
- owningMTB: MultipleTimeBase [1]
specifies the multiple time base that owns this time base

Attributes

- nature: TimeNatureKind [1]
specifies whether the set of owned instants is discrete or dense.

Semantics

A time base represents an ordered set of instants. It is the building block of the time structure.

Constraints

No additional constraints

F.3.22 TimeBaseRelation (from MultipleTimeModels)

A time instant relation states that a set of time bases are temporally dependent in some way.

Generalizations

- TimeStructureRelation (from MultipleTimeModels)

Associations

- /relatedTBs: TimeBase[2..*] {ordered}
references the time bases involved in the relation. This is a derived union.

Attributes

- None

Semantics

A time instant relation states that a set of time bases are temporally dependent in some way. More precisely, some instants of the time bases are temporally related. The related time bases must be directly or indirectly owned by the multiple time base owning this time base relation. This constraint is expressed in the MultipleTimeBase description (constraint [1], page 451). This is an abstract class.

F.3.23 TimedAction (from TimeRelatedEntities:: TimedProcessingModels::Timed Processings)

TimedAction is a generic concept for modeling action that have known start and finish times or a known duration, and whose instants and durations are bound to clocks.

Generalizations

- TimedProcessing (from TimeRelatedEntities::TimedProcessingModels::TimedProcessings).
- Action (from CoreElements::Causality::CommonBehavior).

Associations

- None

Attributes

- None

Semantics

TimedAction is a generic concept for modeling actions that have known start and finish times or a known duration, and whose instants and durations are bound to clocks. This is an abstract class.

F.3.24 TimedBehavior (from TimeRelatedEntities::TimedProcessingModels::Timed Processings)

TimedBehavior is a generic concept for modeling behavior that have known start and finish times or a known duration, and whose instants and durations are bound to clocks.

Generalizations

- TimedProcessing (from TimeRelatedEntities::TimedProcessingModels::TimedProcessings).
- Behavior (from CoreElements::Causality::CommonBehavior).

Associations

- None

Attributes

- None

Semantics

TimedBehavior is a generic concept for modeling behaviors that have known start and finish times or a known duration, and whose instants and durations are bound to clocks. This is an abstract class.

F.3.25 TimedConstraint (from TimeRelatedEntities::TimedConstraints)

TimedConstraint is an abstract superclass of TimedInstantConstraint and TimedDurationConstraint. It allows to constraint when an event may occur or constraint the duration of some execution or even constraint the temporal distance between two event occurrences.

Generalizations

- NfpConstraint (from NFPs::NFP_Annotation)
- TimedElement (from TimedElements)

Associations

- None

Attributes

- None

Semantics

TimedConstraint is an abstract superclass of TimedInstantConstraint and TimedDurationConstraint. It allows to constraint when an event may occur or constraint the duration of some execution or event constraint the temporal distance between two event occurrences. Since a timed constraint is a timed element, it refers to clocks.

F.3.26 TimedDurationConstraint (from TimeRelatedEntities::TimedConstraints)

A TimedDurationConstraint defines a constraint on the duration of some execution or the temporal distance between two event occurrences.

Generalizations

- TimedConstraint (from TimedConstraints)

Associations

- specification: DurationPredicate [1]specification of the constraint. Redefines NFPs::NFP_Annotation::NfpConstraint::specification.

Attributes

- None

Semantics

A TimedDurationConstraint defines a constraint on the duration of some execution or the temporal distance between two event occurrences.

F.3.27 TimedDurationObservation (from TimeRelatedEntities::TimedObservations)

A TimedDurationObservation denotes some interval of time, observed on one clock or two clocks.

Generalizations

- TimedObservation (from TimedObservations)

Associations

- eocc: CoreElements::Causality::RunTimeContext::EventOccurrence [0..2]
when defined, specifies the two event occurrences between which the duration is observed.
- exc: CoreElements::Causality::RunTimeContext:: BehaviorExecution [0..1]
when defined, specifies an execution. The observed duration is between the occurrences of the start and the finish event of this execution.
- stim: CoreElements::Causality::Communication:: Request [0..1]
when defined, specifies a request. The duration is between the sending and the receipt of this message.

Attributes

- obsKind: EventKind [0..2] specifies the kind of the observed events.

Semantics

A TimedDurationObservation denotes some interval of time, associated with execution, request, or two event occurrences, and observed on one clock or two clocks. The latter case occurs for instance when a message is sent to a distant site, with a receiver clock distinct from the sender clock. The duration may be the time elapsed between the occurrences of the start and the finish events of an execution. The duration may also be the time elapsed between two of the three events associated with a message (its sending, its receipt, and the start of its processing by the receiver). More generally, the duration may be the time elapsed between the occurrences of two distinct events.

Constraints

[1] A TimedDurationObservation is an observation of one thing and only one among an execution, a request or a pair of event occurrences.

exc->union(stim)->union(eocc)->notEmpty() and

exc->notEmpty() implies stim->union(eocc)->isEmpty() and

stim->notEmpty() implies exc->union(eocc)->isEmpty() and

eocc->notEmpty() implies (exc->union(stim)->isEmpty() and

eocc->size() = 2)

[2] A TimedDurationObservation of an execution refers to one clock only.

exc->notEmpty() implies on->size() = 1

[3] A TimedDurationObservation of two event occurrences refers to one or two clocks.

eocc->notEmpty() implies **on->size() = 1** or **on->size() = 2**

F.3.28 TimedElement (from TimeRelatedEntities::TimedElements)

TimedElement is an abstract class, generalization of all other timed concepts. It associates a non empty set of clocks with a model element.

Generalizations

- ModelElement (from NFP_Annotation)

Associations

- on: TimeAccesses::Clocks::Clock [1..*] set of clocks through which the model element is related to time.

Semantics

TimedElement is an abstract class, generalization of all other timed concepts. It associates a non empty set of clocks with a model element. The semantics of the association with clocks depends on the kind of timed element.

F.3.29 TimedEvent (from TimeRelatedEntities::TimedEventModels::TimedEvents)

A TimedEvent is an event whose occurrences are bound to clocks.

Generalizations

- Event (from CoreElements::Causality::CommonBehavior).
- TimedElement (from TimedElements).

Associations

- every: CVS::DurationValueSpecification [0..1]
optional DurationValueSpecification which specifies the duration value that separates the successive occurrences of this timed event.
- when: CVS::ClockedValueSpecification [1]ClockedValueSpecification which specifies the instant value of the first occurrence of this timed event. The ClockedValueSpecification is a DurationValueSpecification if the isRelative attribute is true, otherwise it is an InstantValueSpecification.

Attributes

- isRelative: Boolean [1]
if true the time value is relative else it is absolute.
- repetition: Integer [0..1]
it is an optional repetition factor. When defined, repetition is the number of successive occurrences of the TimedEvent. Its absence is interpreted as an unbounded repetition.

Semantics

A TimedEvent is an event whose occurrences are bound to clocks. The when property specifies the instant value of the first occurrence of this TimedEvent. The every optional property specifies repetitive occurrences.

Constraints

[1] The `isRelative` attribute determines the kind of `ClockedValueSpecification`.

if `isRelative` then `when.ocIsTypeOf(DurationValueSpecification)` else `when.ocIsTypeOf(InstantValueSpecification)` endif

[2] The optional repetition property of a `TimedEvent` must be not defined when `every` is not defined.

`every->isEmpty()` implies `repetition->isEmpty()`

F.3.30 TimedEventOccurrence (from TimeRelatedEntities::TimedEventModels::TimedEventOccurrences)

This is a generic concept of an event occurrence that may be assigned an instant value on clocks.

Generalizations

- `EventOccurrence` (from `CoreElements::Causality::RunTimeContext`).
- `TimedElement` (from `TimedElements`).

Associations

- `at: TimeAccesses::TimeValues::InstantValue[1..*]`
instant values of this `TimedEventOccurrence` on one of its on clocks.

Attributes

- None

Semantics

A `TimedEventOccurrence` is an `EventOccurrence` and a `TimedElement`. As a `TimedElement`, it refers to clocks. The `at` property specifies the `InstantValue` of the event occurrence of this `TimedEventOccurrence` on any of its on clocks.

Constraints

[1] The `Clock` of an `at InstantValue` is also a `on Clock` of this `TimedOccurrenceEvent`.

`on->includesAll(at.onClock)`

[2] All the `at` instant values are specified on different clocks.

`at->forAll(iv, jv | iv <> jv implies iv.onClock <> jv.onClock)`

F.3.31 TimedExecution (from TimeRelatedEntities::TimedProcessingModels::TimedExecutions)

This is a generic concept of an execution that may be assigned start and finish instant values and duration values on clocks.

Generalizations

- `ExecutionSpecification` (from `CoreElements::Causality::RunTimeContext`).

- TimedElement (from TimedElements).

Associations

- executionDuration: TimeAccesses::DurationValues::DurationValue [1..*]
duration value of the execution of this TimedExecution on one of its on clocks.
- finishInstant: TimeAccesses::TimeValues::InstantValue [1..*]
instant value of the termination of the execution of this TimedExecution on one of its on clocks.
- startInstant: TimeAccesses::TimeValues::InstantValue [1..*]
instant values of the start of the execution of this TimedExecution on one of its on clocks.

Attributes

- None

Semantics

A TimedExecution is an BehaviorExecutionSpecification and a TimedElement. As a TimedElement, it refers to clocks. The startInstant (finishInstant, respectively) property specifies the InstantValue of the start (finish, respectively) event occurrence of the execution of this TimedExecution on one of its on clocks. The executionDuration property specifies the DurationValue of the execution of this TimedExecution on one of its on clocks.

Constraints

[1] The Clock of a startInstant InstantValue is also a on Clock of this TimedExecution.

on -> includesAll(startInstant.onClock)

[2] The Clock of a finishInstant InstantValue is also a on Clock of this TimedExecution.

on -> includesAll(finishInstant.onClock)

[3] The Clock of an executionDuration InstantValue is also a on Clock of this TimedExecution.

on -> includesAll(executionDuration.onClock)

F.3.32 TimedInstantConstraint (from TimeRelatedEntities::TimedConstraints)

A TimedInstantConstraint defines a constraint on when an event may occur.

Generalizations

- TimedConstraint (from TimedConstraints)

Associations

- specification: InstantPredicate [1]specification of the constraint. Redefines NFPs::NFP_Annotation::NfpConstraint::specification.

Attributes

- None

Semantics

A `TimedInstantConstraint` defines a constraint on when an event may occur.

F.3.33 `TimedInstantObservation` (from `TimeRelatedEntities::TimedObservations`)

A `TimedInstantObservation` denotes an instant in time, observed on a given clock.

Generalizations

- `TimedObservation` (from `TimedObservations`)

Associations

- `eocc: CoreElements::Causality::RunTimeContext::EventOccurrence [1]` observed event occurrence.

Attributes

- `obsKind: EventKind [0..1]` specifies the kind of the observed event.

Semantics

A `TimedInstantObservation` denotes an instant in time, associated with an event occurrence and observed on a given clock. The `obsKind` attribute may specify the kind of the observed event.

Constraints

[1] A `TimedInstantObservation` refers to one clock only.

`on->size() = 1`

F.3.34 `TimedMessage` (from `TimeRelatedEntities::TimedProcessingModels::TimedProcessings`)

`TimedMessage` is a generic concept for modeling communications that have known start, finish or consumption times or a known duration, and whose instants and durations are bound to clocks.

Generalizations

- `TimedProcessing` (from `TimeRelatedEntities::TimedProcessingModels::TimedProcessings`).
- `Request` (from `CoreElements::Causality::Communication`).

Associations

- None

Attributes

- None

Semantics

TimedMessage is a generic concept for modeling communications that have known start, finish or consumption times or a known duration, and whose instants and durations are bound to clocks. This is an abstract class.

F.3.35 TimedObservation (from TimeRelatedEntities::TimedObservations)

TimedObservation is an abstract superclass of TimedInstantObservation and TimedDurationObservation. It allows time expressions to refer to either in a common way.

Generalizations

- TimedElement (from TimedElements)

Associations

- observationContext
- CoreElements::Causality::RunTimeContextModel::CompBehaviorExecution [0..1]
runtime context of the observation.

Attributes

- None

Semantics

TimedObservation is an abstract superclass of TimedInstantObservation and TimedDurationObservation. It allows time expressions to refer to either in a common way. Since a timed observation is a timed element, it refers to clocks. The observation is made in the context of a (sub)system behavior execution. This execution can be represented, for instance, by a sequence diagram. When the observationContext is not defined, the observation is valid for any behavior execution.

F.3.36 TimedProcessing (from TimeRelatedEntities::TimedProcessingModels::Timed-Processings)

TimedProcessing is a generic concept for modeling activities that have known start and finish times or a known duration, and whose instants and durations are bound to clocks.

Generalizations

- TimedElement (from TimedElements)

Associations

- duration: CVS::DurationValueSpecification [0..1]
optional DurationValueSpecification which specifies the duration value of the execution of this timed processing.
- finish: CoreElements::Causality::CommonBehavior::Event [0..1]
optional event whose occurrences denote the termination of execution of this TimedProcessing.
- start: CoreElements::Causality::CommonBehavior::Event [0..1]
optional event whose occurrences denote the start of execution of this TimedProcessing.

Attributes

- None

Semantics

TimedProcessing is a generic concept for modeling activities that have known start and finish times or a known duration, and whose instants and durations are bound to clocks.

This is an abstract class.

Constraints

[1] Not all 3 properties duration, start, finish can be absent.

(duration->isEmpty() implies start->notEmpty() and finish->notEmpty())and

((start->isEmpty() and finish->isEmpty()) implies duration->notEmpty())

F.3.37 TimeInstantRelation (from MultipleTimeModels)

A time instant relation states that junction instants of a set are temporally related in some way.

Generalizations

- TimeStructureRelation (from MultipleTimeModels)

Associations

- /relatedJIs: JunctionInstant[0..*] {ordered}junction instants involved in the relation. This is a derived union.

Attributes

- None

Semantics

A time instant relation states that junction instants of a set are temporally related in some way. The concrete relation can be coincidence, precedence, or membership of a time interval. The related junction instants must be owned by time bases directly or indirectly included in the multiple time base owing this time instant relation. This constraint is expressed in the MultipleTimeBase description (constraint [2], page 451). This is an abstract class.

F.3.38 TimeInterval (from MultipleTimeModels)

A time interval denotes a set of junction instants belonging to a time base and characterized by its lower and upper bound.

Generalizations

- None

Associations

- lower:JunctionInstant [1] lower bound of the interval.

- upper:JunctionInstant [1] upper bound of the interval.
- base:TimeBase [1] time base on which the interval is defined.

Attributes

- isLowerOpen:Boolean [1] = false
specifies whether the lower bound is in the interval or not. When true, the lower bound is not in the interval. The default value is false.
- isUpperOpen:Boolean [1] = false
specifies whether the upper bound is in the interval or not. When true, the upper bound is not in the interval. The default value is false.

Semantics

A time interval of a time base denotes the set of junction instants belonging to this time base and temporally after the lower junction instant and before the upper junction instants. Two Booleans indicate whether the bounds belong or not to the interval. Note that the bounds and the members are restricted to junction instants because they are the only observable instants.

Constraints

[1] The lower and the upper bounds are owned by the time base of the time interval.

(lower.tb = base) and (upper.tb = base)

F.3.39 TimeIntervalMembership (from MultipleTimeModels)

A time interval membership relation states that junction instants of a set are within a given time interval.

Generalizations

- TimeInstantRelation (from MultipleTimeModels)

Associations

- members:JunctionInstant [0..*]
set of junction instants included in a time interval or coincident with a junction instant in the time interval. Subsets TimeInstantRelation::relatedJIs.
- timeInterval:TimeInterval [1]
specifies the including time interval.

Attributes

- None

Semantics

A time interval membership relation states that junction instants of a set are within a given time interval. Within must be interpreted in a broad sense: A member junction instant can be directly in the given time interval or coincident with a junction instant member of the interval.

F.3.40 TimeIntervalValue (from TimeAccesses::TimeValues)

A time interval value is a set of instants values specified by a pair of instant values, which define the bounds of the interval.

Generalizations

- None

Associations

- denotedTimeInterval: TimeInterval [0..*]
time intervals denoted by this time interval value.
- max: InstantValue [1]
instant value which stands for the upper bound of this time interval value.
- min: InstantValue [1]
instant value which stands for the lower bound of this time interval value.

Attributes

- isMinOpen: Boolean [1] = false
specifies whether the minimal instant value is in this time interval value or not. When this attribute is true, then the minimal instant value is not in the interval. The default value is false.
- isMaxOpen: Boolean [1] = false
specifies whether the maximal instant value is in the interval or not. When this attribute is true, then the maximal instant value is not in the interval. The default value is false.

Semantics

A time interval value is a set of instants values specified by a pair of instant values. A time interval value denotes 0 or many time intervals in the time base associated with the onClock clock of its bounds. When the onClock clock has a maximal value, due to clock roll-over, a time interval value may denote many time intervals.

When used in a time value specification, a time interval value designates any time value of the interval (including or not the bound values according to the isMinOpen et isMaxOpen attribute values).

Constraints

[1] Min and max instant values of this time interval value have the same onClock clock.

`min.onClock = max.onClock`

F.3.41 TimeNatureKind (from BasicTimeModels)

TimeNatureKind is an enumeration type that defines literals used to specify the nature discrete or dense of a time base or a time value.

Generalizations

- None

Literals

- discrete indicates that the typed elements are from a discrete set.
- dense indicates that the typed elements are from a dense set.

F.3.42 TimeStandardKind (from TimeAccesses::ChronometricClocks)

TimeStandardKind is an enumeration type that defines literals used to specify the standard "systems of time" adopted for a chronometric clock.

Generalizations

- None

Literals

- GPS General Positioning System, not adjusted for leap seconds
- Local Local Time
- Sidereal Sidereal Time
- TAI International Atomic Time scale, a statistical timescale based on a large number of atomic clocks
- TCB Barycentric Coordinate Time
- TCG Geocentric Coordinate Time
- TDB Barycentric Dynamical Time
- TT Terrestrial Time
- UT0 Universal Time 0
- UT1 Universal Time 1
- UTC Coordinated Universal Time

F.3.43 TimeStructureRelation (from MultipleTimeModels)

A time structure relation states that junction instants of different time bases are temporally related in some way. The relation applies either to a set of junction instants or to a set of time bases.

Generalizations

- None

Associations

- None

Attributes

- None

Semantics

A time structure relation states that junction instants of different time bases are temporally related in some way. The relation applies either to a set of junction instants or to a set of time bases. The latter case is a convenient way to specify multiple temporal relations between junction instants. This is an abstract class.

F.3.44 TimeValue (from TimeAccesses::TimeValues)

TimeValue is an abstract class for expressing instant values and duration values.

Generalizations

- None

Associations

- onClock: Clock [1]
clock that associating time values to instants.
- unit: NFPs::NFP_Nature::Unit [0..1]
optional unit attached to the time value. When defined, it must be in the acceptedUnits set of the onClock and be used instead of its defaultUnit.

Attributes

- nature: TimeNatureKind [1]
specifies whether the time values associated with the clock take their values in a dense or discrete domain.

Semantics

TimeValue is an abstract class for expressing instant values and duration values. Time values are related to a clock.

F.4 GRM

F.4.1 AccesControlPolicy (from MARTE:GRM::ResourceManagement)

The AccesControlPolicy determines the rules for regulating access to the resources controlled by a broker.

Generalizations

- None

Associations

- None

Attributes

- None

Semantics

The AccesControlPolicy determines the rules for regulating access to the resources controlled by a broker.

F.4.2 AccessControlPolicy (from MARTE:GRM::ResourceManagement)

The ResourceControlPolicy determines the rules for regulating the management of resources.

Generalizations

- None

Associations

- None

Attributes

- None

Semantics

The ResourceControlPolicy determines the rules for regulating the management of resources, what includes creating, maintaining, and deleting resources.

F.4.3 Acquire(from MARTE:GRM::ResourceTypes)

Acquire represents the allocation of or the access to some "amount" from the resource.

Generalizations

- ResourceService (from MARTE:GRM::ResourceCore).

Associations

- amount: MARTE:GRM::ResourceCore::ResourceAmount [1..*]
amount of resource to which access is demanded.

Attributes

- isBlocking: Boolean [0..1]
indicates whether the call to the service is blocking or not.

Semantics

Acquire corresponds to the allocation of some "amount" from the resource. For example, for a resource representing storage, the amount could be the memory size. As another example, a resource could represent a single element (maximum amount available is "1"), and acquire could be used to model the lock in a mutually exclusive access situation. If the attribute isBlocking is true it indicates that the caller waits until the service is able to allocate or provide the access to the resource demanded. If false, the service return indicating the impossibility of providing immediate access to the amount of resource demanded.

F.4.4 Activate (from MARTE:GRM::ResourceTypes)

Enable the activation of a certain amount of a resource.

Generalizations

- ResourceService (from MARTE:GRM::ResourceCore)

Associations

- amount: MARTE:GRM::ResourceCore::ResourceAmount [1..*]
amount of resource that is to be activated.

Attributes

- None

Semantics

Activate allows for the application of an activation service on a given quantity. For example, activate a communication service with the amount of data to be transferred as a parameter.

F.4.5 ClockResource (from MARTE:GRM::ResourceTypes)

A ClockResource represents a hardware or software entity that is capable of following and evidencing the pace of time upon demand with a prefixed resolution.

Generalizations

- TimingResource (from MARTE::GRM::ResourceTypes)

Associations

- None

Attributes

- None

Semantics

A ClockResource represents a hardware or software entity that is capable of following and evidencing the pace of time upon demand with a prefixed resolution. The services and the concrete mechanisms used by a ClockResource to offer them are to be furtherly refined as necessary according to the hardware or software nature of the clock.

F.4.6 CommunicationEndPoint (from MARTE::GRM::ResourceTypes)

A CommunicationEndPoint represents a mechanism for connecting and delivering data to a communication media.

Generalizations

- CommunicationResource (from MARTE:GRM::ResourceTypes)

Associations

- None

Attributes

- `packetSize: Integer [0..1]` size in bits of the elementary messages that can be inserted in the `CommunicationEndPoint`.
- `bandwidth: NFP_DataTxRate [0..1]` capacity of the communication element when applicable link.
- `packetT: NFP_Duration [0..1]` time to transmit the element used as a communication quantum, usually called a packet, the size in bits of this quantum is described by the attribute `elementSize`.
- `blockT: NFP_Duration [0..1]` time the `communicationMedia` is blocked and cannot transmit due to the transmission of one communication quantum.
- `transmMode: MARTE_Library::MARTE_DataTypes::TransmModeKind [0..1]` defines the transmission mode, one of the following values: {simplex, half-duplex, full-duplex}.

Semantics

A `CommunicationEndPoint` acts as a terminal for connecting to a communication media, and it is characterized by the size of the packet handled by the endpoint. This size may or may not correspond to the media element size. Concrete services provided by a `CommunicationEndPoint` include the sending and receiving of data, as well as a notification service able to trigger an activity in the application.

F.4.7 CommunicationMedia (from MARTE::GRM::ResourceTypes)

A `CommunicationMedia` represents the mean to transport information from one location to another.

Generalizations

- `CommunicationResource` (from `MARTE:GRM::ResourceTypes`)

Associations

- None

Attributes

- `elementSize: Integer [0..1]` size in bits of the elementary messages that can be transmitted.

Semantics

The fundamental service of a `CommunicationMedia` is to transport information (e.g. message of data) from one location to another. It has as an attribute the size of the elements transmitted; as expected, this definition is related to the resource base clock. For example, if the communication media represents a bus, and the clock is the bus speed, "element size" would be the width of the bus, in bits. If the communication media represents a layering of protocols, "element size" would be the frame size of the uppermost protocol.

F.4.8 CommunicationResource (from MARTE::GRM::ResourceTypes)

A `CommunicationResource` generalizes the two kinds of communication resources defined. It holds a collection of communication services.

Generalizations

- Resource (from MARTE:GRM::ResourceCore)

Associations

- None

Attributes

- None

Semantics

A CommunicationResource generalizes the two kinds of communication resources defined, communicationMedia and communicationEndpoint. It represents any resource used for communication and may be considered as a collector of communication services.

F.4.9 ComputingResource (from MARTE:GRM::ResourceTypes)

A ComputingResource represents either virtual or physical processing devices capable of storing and executing program code. Hence its fundamental service is to compute.

Generalizations

- Resource (from MARTE:GRM::ResourceCore).

Associations

- None

Attributes

- None

Semantics

A ComputingResource represents either virtual or physical processing devices capable of storing and executing program code. Hence its fundamental service is to compute, which in fact means to change the values of data without changing their location. It is active and protected.

Constraints

[2] isActive is true and isProtected is true.

F.4.10 ConcurrencyResource (from MARTE:GRM::ResourceTypes)

A ConcurrencyResource is a protected active resource that is capable of performing its associated flow of execution concurrently with others, all of which take their processing capacity from a potentially different protected active resource (eventually a ComputingResource). Concurrency may be physical or logical, when it is logical the supplying processing resource needs to be arbitrated with a certain policy.

Generalizations

- Resource (from MARTE:GRM::ResourceCore).

Associations

- None

Attributes

- None

Semantics

A ConcurrencyResource is a protected active resource that is capable of performing its associated flow of execution concurrently with others, all of which take their processing capacity from a potentially different protected active resource (eventually a ComputingResource). Concurrency may be physical or logical, when it is logical the supplying processing resource needs to be arbitrated with a certain policy. This root concept is further specialized in the Scheduling package.

Constraints

[3] isActive is true and isProtected is true.

F.4.11 DeviceResource (from MARTE:GRM::ResourceTypes)

A DeviceResource typically represents an external device that may be manipulated or invoked by the platform, but whose internal behavior is not a relevant part of the model under consideration.

Generalizations

- Resource (from MARTE:GRM::ResourceCore)

Associations

- None

Attributes

- None

Semantics

A DeviceResource typically represents an external device that may require specific services in the platform for its usage and/or management. Active device resources may also be used to represent external specific purpose processing units, whose capabilities and responsibilities are somehow abstracted away. The implicit assumption is that their internal behavior is not a relevant part of the model under consideration.

F.4.12 DynamicUsage (from MARTE::GRM::ResourceUsages)

A DynamicUsage represents the sequence or causal flow of usages that may occur in response to an UsageDemand.

Generalizations

- Behavior (from MARTE::CoreElements::Causality::CommonBehavior).

Associations

- None

Attributes

- None

Semantics

A DynamicUsage represents the sequence or causal flow of usages that may occur in response to an UsageDemand. It is a kind of behaviour, whose actions make use of one or more resources along its execution. A few concrete forms of usage are defined at this level of specification; those are aimed to represent the consumption of memory, the time taken from a CPU, the energy from a power supply and the number of bytes to be sent through a network.

F.4.13 GetAmountAvailable (from MARTE:GRM::ResourceTypes)

GetAmountAvailable returns the amount of the resource that is currently available.

Generalizations

- ResourceService (from MARTE:GRM::ResourceCore)

Associations

- None

Attributes

- None

Semantics

- GetAmountAvailable returns the amount of the resource that is currently available.

F.4.14 MutualExclusionProtocol (from MARTE::GRM::Scheduling)

It provides or determines the set of rules necessary to arrange contending access to shared protected resources at run time.

Generalizations

- AccesControlPolicy (from MARTE:GRM::ResourceManagement).

Associations

- None

Attributes

- protocol: MARTE:GRM::Scheduling::ProtectProtocolKind [1]
concrete type of protection protocol used.
- otherProtectProtocol: String [0..1]
this string is used by the modeller to specify the protection protocol used when it is none of the

included in the ProtectProtocolKind enumerated type.

Semantics

MutualExclusionProtocols are defined in scheduling theory to avoid or minimize the priority inversion problem with the minimum impact on the pessimism of the analysis technique to apply. The protocols are to be implemented by the scheduler and consequently they must be compatible with the scheduling policy implemented by them. To be effectively applied some of them require each resource to be characterize with additional ProtectionParameters, which typically represent the scope of schedulable resources that will make use of the passive mutually exclusive resource.

F.4.15 MutualExclusionResource (from MARTE::GRM::Scheduling)

A MutualExclusiveResource is a kind of synchronization resource that represents the contention in the access to common usually passive resources at run-time.

Generalizations

- SynchResource (from MARTE::GRM::ResourceTypes).

Associations

- protocol: MARTE::GRM::Scheduling::MutualExclusioProtocol [1]
protection protocol used by the scheduler to regulate the access to the MutalExclusionResource.
- protectParams: MARTE::GRM::Scheduling::ProtectionParameters [0..*]
concrete parameters to be passed to the scheduler.
- scheduler: MARTE::GRM::Scheduling::Scheduler [0..1]
scheduler in charged of imposing the protocol rules.

Attributes

- protocol: MARTE:GRM::Scheduling::ProtectProtocolKind [1]
concrete type of protection protocol used.

Semantics

When the executionBehaviors of concurrencyResources need to access common protected resources, the underlying scheduling mechanisms are typically implemented using some form of synchronization resource, (semaphore, mutex, etc.) with a protecting protocol to avoid priority inversions. Other solutions avoid this concurrency issue by creating specific schedules which order the access in advance. Whichever mechanism is used, the pertinent abstraction at this level of specification requires at least the identification of the common resource, its protecting mechanism, and the associated protocol; this is what the MutualExclusionResource defines. Its associated protocol, represented by MutualExclusiveProtocol, is derived from the policy associated to the scheduler that manages it, and the parameters required by the protocol are represented by the ProtectionParameters element.

F.4.16 ProcessingResource (from MARTE::GRM::Scheduling)

A ProcessingResource generalizes the concepts of CommunicationMedia, ComputingResource, and active DeviceResource.

Generalizations

- Resource (from MARTE::GRM::ResourceCore)

Associations

- mainScheduler: MARTE::GRM::Scheduling::Scheduler [0..1]
scheduler that share the processing capacity brought in by the processing resource.

Attributes

- speedFactor: NFP_Real [0..1] = (value=1.0)
this number gives a linear approximation of the relative speed of the unit as compare to the reference one. The reference processing resource is determined as one with speedFactor equal to 1.0.

Semantics

A ProcessingResource generalizes the concepts of CommunicationMedia, ComputingResource, and active DeviceResource. It introduces an element that abstracts the fundamental capability of performing any behavior assigned to the active classifiers of the modeled system. Fractions of this capacity are brought to the SchedulableResources that require it.

The speedFactor attribute is a linear approximation of the relative speed of the unit as compare to the reference one. The reference processing resource is determined by setting its speedFactor to 1.0.

F.4.17 ProtectParameters (from MARTE::GRM::Scheduling)

This class holds the parameters that are necessary for two of the more typical protocols that need them; the priority ceiling and the stack based protocols.

Generalizations

- None

Associations

- None

Attributes

- priorityCeiling: Integer [0..1]
ceiling of the resource, used in the Priority Ceiling Protocol.
- preemptionLevel: UnlimitedNatural [0..1]
preemption level of the resource, used in the Stack Based Protocol.

Semantics

This is a utility class used to provide the required ceilings for these protocols. The stack based protocol is the EDF compatible version of the priority ceiling protocol, and since both used different nomenclature to hold the required ceiling, both fields have been included: the ceiling and the preemption level.

F.4.18 ProtectProtocolKind (from MARTE::GRM::Scheduling)

This class is an enumerated value with the shared variables protection protocols most widely known.

Literals

- FIFO
- NoPreemption
- PriorityCeiling
- PriorityInheritance
- StackBased
- Undef
- Other

F.4.19 Release (from MARTE:GRM::ResourceTypes)

Release represents the de-allocation or liberation of some "amount" from the resource.

Generalizations

- ResourceService (from MARTE:GRM::ResourceCore)

Associations

- amount: MARTE:GRM::ResourceCore::ResourceAmount [1..*] amount of resource that is released.

Attributes

- None

Semantics

Release corresponds to the de-allocation of some "amount" from the resource. For example, for a resource representing storage, the amount could be the memory size. As another example, a resource could represent a single element (maximum amount available is "1"), and release could be used to model the unlock in a mutually exclusive access situation.

F.4.20 Resource (from MARTE::GRM::ResourceCore)

A resource represents a physically or logically persistent entity that offers one or more services. Resources and its services are the available means to perform the expected duties and/or satisfy the requirements for which the system under consideration is aimed.

Generalizations

- BehavouredClassifier (from MARTE::CoreElements::Causality::CommonBehavior).
- AnnotatedElement (from MARTE::NFPs::NFP_Annotation).

Associations

- **referenceClocks:** TimeModel::TimeAccesses::Clocks Clock [0..*]
clocks that serve as time base for the services that the resource may provide.
- **pServices:** ResourceService [0..*]
set of services provided by the resource.
- **instance:** ResourceInstance [0..*]
set of Instances provided by the resource. (Inherited from MARTE::CoreElements::Foundations).
- **provided:** MARTE::NFP_Modelig::NFP_Declaration::NFP
set of non-functional properties provided. Subsets
MARTE::NFPs::NFP_Annotation::AnnotatedElement.nfpDeclaration.
- **required:** MARTE::NFP_Modelig::NFP_Declaration::NFP
set of non-functional properties required. Subsets
MARTE::NFPs::NFP_AnnotationAnnotatedElement.nfpDeclaration.
- **manager:** ResourceManager [0..1]
link to a manager of the instances of the resource.
- **broker:** ResourceBroker [0..*]
link to a broker of the instances of the resource.

Attributes

- **resMult:** Integer[0..1]
resource multiplicity is used to express the limited nature of an aggregated multi elementary resource. When used it indicates the maximum number of instance of the elementary units of a particular type of resource that are available through its corresponding services.
- **isProtected:** Boolean [0..1]
if true implies the necessity of arbitrating access to the resource or its services.
- **isActive:** Boolean [0..1]
if true it implies that the resource has its own course of action.

Semantics

A resource can be a "black box", in which case only the provided services are visible, or a "white box", in which case its internal structure, in terms of lower level resources, may be visible, and the services provided by the resource may be detailed based on collaborations of these lower level resources.

Note that in the case of the platform provider for example, it is up to the modeler to represent it as:

- A black box resource (e.g. a real-time operating system), which abstracts the hardware hence considered as internal elements.
- A collaboration between a software layer and a hardware layer.
- A collaboration between basically hardware elements. In this case, software features of the execution platform may be represented by overheads on raw hardware performance figure.
- Any combination of these previous approaches depending on the type of development and analysis method applied by the user.

The rationale for deciding if an element in the execution platform should be represented as a resource in the platform model is more related to its criticality in terms of real-time behavior, rather than to its software or hardware nature. Therefore, the interface (i.e., the set of services) provided by the execution platform as a whole may be much simpler than the API (Application Programming Interface) visible to the application software. Of course, a model library describing a given platform may provide several views, corresponding to different anticipated use cases for the platform.

A resource may be structurally described in terms of its internal resources - this is represented by the "owner-ownedElement" association in Resource transitively inherited from ModelElement.

F.4.21 ResourceAmount (from MARTE::GRM::ResourceCore)

A ResourceAmount represents a generic quantity of the "amount" provided by the resource.

Generalizations

- ModelElement (from MARTE::CoreElements::Foundations).

Associations

- None

Attributes

- None

Semantics

A ResourceAmount represents a generic quantity of the "amount" provided by the resource. This may be mapped to any significant quantification of the resource, like memory units, utilization, power, etc. This is an abstract class.

F.4.22 ResourceBroker (from MARTE:GRM::ResourceManagement)

The resourceBroker, is a kind of resource that is responsible for allocation and de-allocation of a set of resource instances (or their services) to clients according to a specific access control policy.

Generalizations

- Resource (from MARTE:GRM::ResourceCore).

Associations

- brokedResource: MARTE:GRM::ResourceCore::Resource [1..*]
resources to which the broker controls access.
- accCtrlPolicy: MARTE:GRM::ResourceManagement::AccessControlPolicy [1..*]
policy used to regulate access to the resources controlled by the broker.

Attributes

- None

Semantics

The resourceBroker, is a kind of resource that is responsible for allocation and de-allocation of a set of resource instances (or their services) to clients according to a specific access control policy. For example, a memory manager will allocate memory from a heap upon request from a client and also return it back into the heap once the client no longer needs it. The access control policy determines the criteria for determining and making effective the provision of resources, it can impose limitations on the prioritization of competing requests, or on the amount of memory provided to individual clients, etc. After being created and initialized, the resources are typically handed over to a resource broker. In most practical cases, the resource manager and the resource broker are the same entity. However, since this is not always true the two concepts are modeled separately (they can be easily combined by designating the same entity as serving both purposes).

F.4.23 ResourceInstance (from MARTE::GRM::ResourceCore)

A resource instance represents the realization of a concrete resource. It can be used to describe generic elements of a concrete platform or designated modeling elements at a certain level of specification meaningful to the modeler in order to consider its properties or services as offered to others.

Generalizations

- AnnotatedElement (from MARTE::NFPs::NFP_Annotation).
- Instance (from MARTE::CoreElements::Foundations).

Associations

- type: MARTE::GRM::ResourceCore::Resource [1..*]
set of classifiers to whose specifications the instance is conformant.

Attributes

- exeServices: ResourceServiceExecution [0..*]
set of represented run-time performing services of a resource that are to be considered for one of its particular instances.

Semantics

A ResourceInstance is the concretization of a resource or resources, and is to be conformant with the specification of those resources that it instantiates. It assumes the role of an instance in the classifier-instance modeling pattern, and consequently adopts the corresponding semantics. In general it is used to represent the items of a resource that are modeled at configuration time, instantiated at deployment time, and managed at run time.

F.4.24 ResourceManager (from MARTE:GRM::ResourceManagement)

The ResourceManager, is responsible for creating, maintaining, and deleting resources according to a resource control policy.

Generalizations

- Resource (from MARTE:GRM::ResourceCore).

Associations

- managedResource: MARTE:GRM::ResourceCore::Resource[1..*]
set of resources that are managed.
- resCtrlPolicy: MARTE:GRM::ResourceManagement::ResourceControlPolicy[1..*]
policy used to regulate the management of resources.

Attributes

- None

Semantics

The ResourceManager, is responsible for creating, maintaining, and deleting resources according to a resource control policy. For example, a buffer pool manager is responsible for creating a set of buffers from one or more chunks of heap memory. Once created and initialized, the resources are typically handed over to a resource broker. In most practical cases, the resource manager and the resource broker are the same entity. However, since this is not always true the two concepts are modeled separately (they can be easily combined by designating the same entity as serving both purposes).

F.4.25 ResourceReference (from MARTE:GRM::ResourceCore)

A ResourceReference is an abstract class that will be used to create links to concrete instances of resources in order to manage them.

Generalizations

- ModelElement (from MARTE::CoreElements::Foundations).

Associations

- None

Attributes

- None

Semantics

A ResourceReference provides a way to designate instances of a resources that will be created and eliminated at run-time. This is an abstract class.

F.4.26 ResourceService (from MARTE::GRM::ResourceCore)

A ResourceService represent the behaviors of interest for a certain kind of resource.

Generalizations

- Behavior (from MARTE::CoreElements::Causality::CommonBehavior).

Associations

- instance: ResourceServiceExecution [0..*]
set of run-time instances of the service that may be performed in the context of the resource associated

(Inherited from MARTE::CoreElements::Foundations).

- context: from MARTE:GRM::ResourceCore::Resource [1]
the resource in whose context the service is specified.

Attributes

- None.

Semantics

ResourceServices are the available means for a Resource to manifest, and then perform, its expected duties and/or responsibilities, to further satisfy the requirements for which it is in place. ResourceServices are expressed as behaviors associated to the resource, which also provides the structural context for them.

F.4.27 ResourceUsage (from MARTE::GRM::ResourceUsages)

A UsageDemand represents the run-time mechanism that effectively requires the usage of the resource.

Generalizations

- None

Associations

- requiredAmount: MARTE::GRM::ResourceUsages::UsageTypedAmount [0..*]
list of different types of amounts of resources, that are expressed by means of non-Functional properties used to characterize the magnitudes demanded by the usage.
- usedResources: MARTE::GRM::CoreResource::Resource [0..*]
list of resource used.
- workload: MARTE::GRM::ResourceUsages::UsageDemand [0..*]
the set of events to which the usage responds.

Attributes

- None

Semantics

When resources are used, their usage may consume part of the "amount" provided by the resource. Taking into account these usages when reasoning about the system operation, is a central task in the evaluation of its feasibility. A ResourceUsage links resources with concrete demands of usage over them. The concept of UsageDemand represents the dynamic mechanism that effectively requires the usage of the resource. Two general forms of usage are defined the StaticUsage and the DinamicUsage, each used according to the specific needs of the model. A few concrete forms of usage are defined at this level of specification; those are aimed to represent the consumption of memory, the time taken from a CPU, the energy from a power supply and the number of bytes to be sent through a network.

F.4.28 SchedPolicyKind (from MARTE:GRM::Scheduling)

This class is an enumerated value with the scheduling policies most widely known.

Literals

- EarliestDeadlineFirst
- FIFO
- FixedPriority
- LeastLaxityFirst
- RoundRobin
- TableDriven
- Undef
- Other

F.4.29 SchedulableResource (from MARTE::GRM::Scheduling)

A SchedulableResource is defined as a kind of ConcurrencyResource with logical concurrency.

Generalizations

- ConcurrencyResource (fromMARTE::GRM::ResourceTypes).

Associations

- schedParams: MARTE::GRM::Scheduling::SchedulingParameters [1]
concrete parameters used to compete for the access to the processing capacity brokered by the scheduler.
- dependentScheduler: MARTE::GRM::scheduling::SecondarySceduler [0..1]
secondary scheduler to which the schedulable resource bring its capacity.
- host: MARTE::GRM::Scheduling::Scheduler [1]
scheduler in which the SchedulableResource is being consider for processing.

Attributes

- None

Semantics

A SchedulableResource is defined as a kind of ConcurrencyResource with logical concurrency. This means that it takes the processing capacity from another active protected resource, usually a ProcessingResource, and competes for it with others linked to the same scheduler under the basis of the concrete scheduling parameters that each SchedulableResource has associated. In the case of hierarchical scheduling, schedulers other than the main scheduler are represented by the SecondaryScheduler concept. This kind of schedulers do not receive processing capacity directly from a processing resource, instead they receive it from a schedulableResource, which is in its turn effectively scheduled by another scheduler. These intermediate schedulableResource, play the role of a virtual processing resource, conducting the fraction of capacity they receive from their host scheduler to its dependent secondaryScheduler.

F.4.30 Scheduler (from MARTE:GRM::Scheduling)

A Scheduler is defined as a kind of ResourceBroker that brings access to its broked ProcessingResource or resources following a certain scheduling policy.

Generalizations

- ResourceBroker (from MARTE:GRM::ResourceManagement).

Associations

- processingUnits: MARTE:GRM::Scheduling::ProcessingResource [1..*]
set of processing resources to which the scheduler controls access. Subsets MARTE:GRM::ResourceManagement:: ResourceBroker .brokedResource.
- schedulableResource: MARTE:GRM::Scheduling::SchedulableResource [0..*]
set of schedulable resources that try to get processing capacity from the ComputingResources controlled by the scheduler.
- policy: MARTE:GRM::Scheduling::SchedulingPolicy [1]
policy used to regulate access to the processing capacity brought in by the ComputingResources controlled by the scheduler. Subsets MARTE:GRM::ResourceManagement::ResourceBroker.accCtrlPolicy.
- host: (from MARTE:GRM::ResourceTypes::ComputingResource [1]
the computing resource on which the artifacts that realize the scheduler are deploy and from which it gets computing power to work.

Attributes

- schedule: OpaqueExpression [0..1] concrete schedule that is to be used by the scheduler.

Semantics

A Scheduler is defined as a kind of ResourceBroker that brings access to its broked ProcessingResource or resources following a certain scheduling policy. The concept of scheduling policy as it is presented here corresponds to the scheduling mechanism described in section 6.1.1 of SPT, since it refers specifically to the order to choose threads for execution.

The attribute host represents the ComputingResource on which the artifacts that realize the scheduler are deploy and from which it gets computing power to work.

The concrete schedule that is to be used by the scheduler may be calculated offline and introduced as an opaque expression or it may be the result of a simulation after applying the scheduling policy and taking traces of the scheduler behavior.

F.4.31 SchedulingParameters (from MARTE::GRM::Scheduling)

Values given to a SchedulableResource to quantify its merits to receive processing capacity in comparison with others scheduled under the same scheduler.

Generalizations

- None

Associations

- None

Attributes

- None

Semantics

Values given to a `SchedulableResource` to quantify its merits to receive processing capacity in comparison with others scheduled under the same scheduler. A fine characterization is necessary to address the wide range of parameters that correspond to each of the different kinds of policies available.

F.4.32 SchedulingPolicy (from MARTE:GRM::Scheduling)

It provides or determines the set of rules necessary to arrange scheduling at run time.

Generalizations

- `AccessControlPolicy` (from `MARTE:GRM::ResourceManagement`).

Associations

- None

Attributes

- `policy`: `MARTE:GRM::Scheduling::SchedulingPolicyKind` [1]
concrete type of policy followed.
- `otherSchedPolicy`: `String` [0..1]
string is used by the modeller to specify the scheduling policy followed when it is none of the included in the `SchedPolicyKind` enumerated type

Semantics

It provides or determines the set of rules necessary to arrange scheduling at run time. The concept of scheduling policy as it is presented here corresponds to the scheduling mechanism described in section 6.1.1 of SPT, since it refers specifically to the order to choose threads for execution.

F.4.33 SecondaryScheduler (from MARTE:GRM::Scheduling)

A `SecondaryScheduler` is defined as a kind of `Scheduler`, for which the processing capacity to share among its schedulable resources is not obtained directly from processing units, but from other schedulable resource instead.

Generalizations

- `Scheduler` (from `MARTE:GRM::Scheduling`).

Associations

- `virtualprocessingUnits`: `MARTE:GRM::Scheduling::SchedulableResource` [1..*]
set of virtual processing resources to whose processing capacity the secondary scheduler controls access.

Attributes

- None

Semantics

The SecondaryScheduler concept is introduced to support hierarchical scheduling schemes. It is conceived as a kind of Scheduler, for which the processing capacity that will be shared among its schedulable resources is not obtained directly from processing units, but from other schedulable resource instead, which is in its turn effectively scheduled by another scheduler. These intermediate schedulableResource, play the role of a virtual processing resource, conducting the fraction of capacity they receive from their host scheduler to its dependent secondaryScheduler.

F.4.34 StaticUsage (from MARTE::GRM::ResourceUsages)

A StaticUsage represents a usage with no temporal assumption eventually occurring in response to an UsageDemand.

Generalizations

- Behavior (from MARTE::CoreElements::Causality::CommonBehavior).

Associations

- None

Attributes

- None

Semantics

A StaticUsage represents a usage with no temporal assumption, in such a way that it may represent the usage that occurs inside a simple action as well as the full usage of a set of resources from the platform due to the operation of the whole system. A few concrete forms of usage are defined at this level of specification; those are aimed to represent the consumption of memory, the time taken from a CPU, the energy from a power supply and the number of bytes to be sent through a network.

F.4.35 StorageResource (from MARTE:GRM::ResourceTypes)

A StorageResource represents the different forms of memory.

Generalizations

- Resource (from MARTE::GRM::ResourceCore).

Associations

- None

Attributes

- elementSize: Integer size in bits of the basic storage unit.

Semantics

A StorageResource represents memory, and its capacity is expressed in number of elements; the size of an individual element in bits must be given. The reference clock in this kind of resources corresponds to the pace at which data is updated in it, and hence it determines the time it takes to access to one individual memory element. The level of granularity in the amount of storage resources represented is up to the model designer. For example, if the storage resource represents a hard disk drive, the element could be a block or a sector, and the speed of the clock to access such element would be directly related to the disk rotation speed. The services provided by a storage resource are intended to move data between memory and a processing unit, which in this case can be a computing resource or a communication endpoint.

F.4.36 SynchResource (from MARTE:GRM::ResourceTypes)

A SynchResource represents the kind of protected resources that serve as the mechanisms used to arbitrate concurrent execution flows, and in particular the mutual exclusive access to shared resources.

Generalizations

- Resource (from MARTE:GRM::ResourceCore)

Associations

- None

Attributes

- None

Semantics

A SynchResource represents the kind of protected resources that serve as the mechanisms used to arbitrate concurrent execution flows, and in particular the mutual exclusive access to shared resources. This general concept is further specialized inside the context of the GRM in the Scheduling package.

Constraints

[1] isProtected is true.

F.4.37 TimerResource (from MARTE:GRM::ResourceTypes)

A TimerResource represents a hardware or software entity that is capable of following and evidencing the pace of time upon demand with a prefixed maximum resolution, at programmable time intervals.

Generalizations

- TimingResource (from MARTE::GRM::ResourceTypes)

Associations

- None

Attributes

- duration: NFP_Duration
interval after which the timer will make evident the elapsed time.
- isPeriodic: Boolean
if true, the timer will indicate the arrival of a new finalization of the programmed interval in a periodic repetitive way. If false, it will do it only one time after it is started.

Semantics

A TimerResource represents a hardware or software entity that is capable of following and evidencing the pace of time upon demand with a prefixed maximum resolution, usually with the usage of its reference clock. The TimerResource will make evident the arrival of the programmed duration time after the instant of its last starting or resetting.

When the attribute is Periodic is set to true the timer will indicate the arrival of a new finalization of the programmed interval in a periodic repetitive way, if set to false it will do it only one time after it is started. As any TimingResource, the services and the concrete mechanisms used by a TimerResource to offer them are to be furtherly refined as necessary according to the hardware or software nature of the timer and its reference clock.

F.4.38 TimingResource (from MARTE:GRM::ResourceTypes)

A TimingResource represents a hardware or software entity that is capable of following and evidencing the pace of time.

Generalizations

- Resource (from MARTE::GRM::ResourceCore).
- ChronometricClock (from MARTE::Time::TimeAccess::ChronometricClocks).

Associations

- start: GRM::ResourceCore::ResourceService [0..1]
service for starting the operation of the TimingResource.
- set: GRM::ResourceCore::ResourceService [0..1]
service for assigning a time value to the TimingResource.
- get: GRM::ResourceCore::ResourceService [0..1]
service for obtaining the time value from the TimingResource.
- reset: GRM::ResourceCore::ResourceService [0..1]
service for re-starting the operation of the TimingResource.
- pause: GRM::ResourceCore::ResourceService [0..1]
service for pausing the operation of the TimingResource.

Attributes

- None

Semantics

A TimingResource represents a hardware or software entity that is capable of following and evidencing the pace of time. It is defined as a kind of chronometric clock, and may represent a clock itself or a timer, in which case it acts according to the clock that it has as a reference. According to the concrete kind of resource or timing mechanism that it represents, the referenced clock may be another chronometric clock or a logical clock, as defined in the time chapter. A TimingResource has concrete services for its management and operation.

F.4.39 UsageDemand (from MARTE::GRM::ResourceUsages)

A UsageDemand represents the dynamic mechanism that effectively requires the usage of the resource.

Generalizations

- None

Associations

- event: MARTE::CoreElements::Causality::CommonBehavior::Event [0..1]
event that induce the demand.
- usage: MARTE::GRM::ResourceUsages::ResourceUsage [0..*]
list of usages demanded by the referenced event.

Attributes

- None

Semantics

The concept of UsageDemand represents the dynamic mechanism that effectively requires the usage of the resource. It links events (that can come from the external environment to concrete usages of the resources describe in the model under consideration.

F.4.40 UsageTypedAmount (from MARTE::GRM::ResourceUsages)

A UsageTypedAmount represents the amount and concrete types of magnitudes that characterize what can be used from a Resource. .

Generalizations

- ResourceAmount (from MARTE:GRM::ResourceCore)

Associations

- None

Attributes

- execTime: NFP_Duration [*] processing time used.
- msgSize: NFP_DataSize [*] number of bytes send.
- allocatedMemory: NFP_DataSize [*] amount of memory allocated.

- usedMemory: NFP_DataSize [*] amount of memory that is required to be available.
- powerPeak:NFP_Power [*] power capability required as available.
- enery:NFP_Energy [*] energy consumed.

Semantics

The concept of UsageTypeAmount is used to collect in one structure all the types of usages that are defined in this specification. Some types are demands that imply effectively the consumption of resources like energy, execTime, msgSize, or allocatedMemory; allocatedMemory can in fact be negative since it may be returned to the system. Others like powerPeak, and usedMemory imply the necessity to have the mentioned amount as available; powerPeak is the maximum power that is demanded, while usedMemory is the amount of memory that is typically temporary allocated (like in the stack for example) to perform an action, but which is promptly returned to the system. The multiplicities allow for different statistical or purpose dependent annotations of the same magnitude.

F.5 Alloc

F.5.1 Allocation (from Allocations)

Allocation is a mechanism for associating elements from a logical context, application model elements, to named elements described in a more physical context, execution platform model elements.

Generalizations

- None

Associations

- impliedConstraint: NFP_Constraint [*]
constraints implied by the allocation.
- source: ApplicationAllocationEnd [1..*]
application model elements being allocated.
- target: ExecutionPlatformAllocationEnd [1..*]
execution platform model elements to which the sources are allocated.

Attributes

- None

Semantics

An Allocation represents either a possible allocation, in which case, a space exploration tool may determine what the best allocations are, or an actual allocation in the system. The context in which the allocate dependency is used should be sufficient to know in which case we are. When it is not the case, the kind of the constraints may help in determining whether the allocation is required, offered, etc.

The purpose of the impliedConstraint association is to explicitly identify what are the constraints that only apply if or when the allocation is performed.

F.5.2 AllocationEnd (from Allocations)

AllocationEnd is an abstract class that identifies elements involved in an allocation.

Generalizations

- None

Associations

- None

Attributes

- None

Semantics

AllocationEnds are elements that have at least one allocation relationship with another element. This is an abstract class, concrete specialized allocation ends are provided to clarify whether the end is a source for the allocation or a target.

F.5.3 ApplicationAllocationEnd (from Allocations)

ApplicationAllocationEnd identifies elements that are sources of an allocation.

Generalizations

- AllocationEnd (from Allocations)

Associations

- /allocatedTo: ExecutionPlatformAllocationEnd[*]
' union of all targets of all allocations into which the ApplicationAllocationEnd is involved as a source.

Attributes

- None

Semantics

ApplicationAllocationEnd identifies application model elements that are allocated to resources. Its allocatedTo attribute is derived from any Allocation dependency and allows for tracing the resources on to which this element is allocated.

F.5.4 ExecutionPlatformAllocationEnd (from Allocations)

ExecutionPlatformAllocationEnd identifies elements that are targets of an allocation.

Generalizations

- AllocationEnd (from Allocations)

Associations

- /allocatedFrom: ApplicationAllocationEnd[*]
union of all sources of all allocations into which the ExecutionPlatformAllocationEnd is involved as a target.

Attributes

- None

Semantics

ApplicationAllocationEnd identifies execution platform model elements that are the target of an Allocation. Its allocatedFrom attribute is derived from any Allocation dependency and allows for tracing the model elements that are allocated.

F.5.5 Refinement (from Allocations)

Refinement is a relationship where a general element is refined into more specialized ones. It is the opposite of an abstraction.

Generalizations

- None

Associations

- general: AllocationEnd [1] element being refined.
- refined: AllocationEnd [1..*] refined elements.
- constraints: NFPs::NFP_Annotation::NFP_Constraint [*] set of constraints implied by the refinement.

Attributes

- None

Semantics

Contrary to an allocation that deals with independent models, refinement works by changing the focus on an underlying similar structure. A refinement applies either to application model elements only or to execution platform model elements only.

Constraint

- [1] If the general end is an ApplicationAllocationEnd then the refined ends must be ApplicationAllocationEnd as well.
- [2] If the general end is an ExecutionPlatformAllocationEnd then the refined ends must also be ExecutionPlatformAllocationEnd.

F.6 GCM

F.6.1 AssemblyConnector

An `AssemblyConnector` represents a specific interaction between ports and/or parts in the context of the definition of a `StructuredComponent`. An assembly connector defines at least two connector ends, which refers to type-compatible ports or components, depending on which element is connected. An assembly connector may be typed by an association defined between components. In that case, it represents a specific instantiation of this association in a composite structure.

Associations

- `endPort: InteractionPort [*]` ports used to connect ports or parts of a `StructuredComponent`.
- `endPart: AssemblyPart [*]` connected parts of a `StructuredComponent`.

Semantics

This concept matches the definition of the `CompositeStructures::InternalStructures::Connector` classifier defined in UML. An assembly connector can be used to link components through ports, in that case both `endPort` and `endPart` association roles are used. They can be also used to directly link components, in that case the `endPort` association role is not used.

F.6.2 AssemblyPart

An `AssemblyPart` is a property that relates to a `StructuredComponent`. It is used to describe that an instance of a `StructuredComponent` is used in the definition of the structure of another one.

Generalizations

- Property (from `MARTE ::Causality::CommonBehavior`).

Semantics

The type attribute of an `AssemblyPart` refers to a `StructuredComponent`. It means that this specific component is instantiated and used in an assembly to define the structure of another `StructuredComponent`.

F.6.3 BFeatureAction

`BFeatureKind` is an enumeration, which literals specify the kind of behavioral features related to message ports.

Literals

- `provided`: the behavioral feature is provided by the port of the owning entity.
- `required`: the behavioral feature is provided by the port of the owning entity.

Semantics

The type attribute of an `AssemblyPart` refers to a `StructuredComponent`. It means that this specific component is instantiated and used in an assembly to define the structure of another `StructuredComponent`.

F.6.4 BroadcastSignalAction

A `BroadcastSignalAction` is an action that sends a signal to other connected components. In that case, connected component ports indicate that they can consume this type of signal.

Generalization

InvocationAction (from MARTE::CoreElements::GeneralComponent).

Associations

- signalToProduce: SignalFeature [1]signal to be produced and broadcasted to other components.

Semantics

This concept matches the BroadcastSignalAction classifier defined in UML.

F.6.5 DirectionKind

DirectionKind is an enumeration, which literals specify the direction of flow elements or signals.. It is used with atomic flow (or message) ports to specify the direction of a flow element or a signal that types the port. It can be also used with non-atomic flow (or message) ports to specify the direction of a flow specification, or the direction of its owned properties.

Literals

- in direction of the information flow is from outside to inside of the owning entity. When related to a signal, it is usual to say that the signal is consumed.
- out direction of the information flow is from inside to outside of the owning entity. When related to a signal, it is usual to say that the signal is produced or published.
- inout bidirectional information flow.

F.6.6 SendFlowAction

A SendFlowAction is an action that sends a flow to other connected components. In that case, connected component ports indicate that they accept this type of flow in input.

Generalizations

- InvocationAction (from MARTE::CoreElements::GeneralComponent).

Associations

- dataToSend: FlowProperty [*] data to send as an array of FlowProperty.

Semantics

This action sends a data flow to other connected components, which accept this type of flow in input. An asynchronous and "fire and forget" communication mode is used: the caller does not wait for data transmission to be completed and acknowledged to continue its execution.

F.6.7 FlowPort

A FlowPort is a concrete kind of InteractionPort used for flow-oriented communications between structured components. A FlowPort may relay incoming, outgoing or bidirectional flows. The nature of the flow can be specified by a property type in the case of an atomic flow port. A flow can be also specified in terms of flow specifications and flow properties, in the case of a non-atomic flow port.

Generalization

- InteractionPort (from MARTE::CoreElements::GeneralComponent).

Attributes

- /isAtomic: Boolean [1] = false
if true, the port is said to be an atomic port, otherwise it is considered as a non-atomic port. An atomic port is typed by a Classifier, Signal, a DataType or a PrimitiveType.
- isConjugated: Boolean [1] = false
if true, the port is said to be a conjugated port. In this case, all the directions of the flow properties (FlowProperty) specified by a FlowSpecification that types a port are relayed in the opposite direction (e.g., an incoming flow property is treated as an outgoing flow property by the FlowPort). By default, the value is false. This attribute applies only to non-atomic ports.
- direction: DirectionKind [0..1]
direction of the port when the port is atomic. In other case, this property is not applicable.

Associations

- specification: FlowSpecification [0..1] flow specification used to type a non-atomic flow port.

Semantics

Flow ports support flow-oriented communications between structured components. A flow port enables to specify the nature of flow that it may relay. A flow port may handle incoming (in), outgoing (out) or bidirectional (inout) flows. If a flow port is atomic, the "type" association role, inherited from Property, is used to specify the nature of the flow and its "direction" attribute is used to specify the direction. If the port is not atomic, the "specification" association role is used to specify the nature of the flow using a flow specification. The flow direction has to be fixed for each flow property owned by the flow specification then. An atomic flow port typed by a Signal, specifying an incoming flow direction, maps to a Reception of the signal. An atomic flow port typed by a Signal, specifying an outgoing flow direction, declares the ability for the port to relay the signal over connectors. This concept matches the FlowPort concept defined in SysML.

Constraints

[1] A conjugated port may be involved in only bidirectional connector, i.e. connector with exactly two connector ends.

[2] If a port is non-atomic, it cannot specify a direction.

`self.isAtomic = false` implies `self.direction->size() = 0`

[3] A conjugated port cannot be an atomic port.

`self.isConjugated = true` implies `self.isAtomic = false`

[4] The type of a non-atomic flow port has to be a flow specification (i.e. an interface stereotyped with "flowSpecification").

F.6.8 FlowProperty

A FlowProperty defines the type and the direction of a single flow element carried through flow ports. It may relate to a Classifier, a Signal, a PrimitiveType or a DataType. A flow property is used by as part of a flow specification to characterize the type of a non-atomic flow port.

Generalization

Property (from MARTE::CoreElements::Foundations).

Attributes

- direction: DirectionKind [1] = in
direction of the flow property: either incoming (in), outgoing (out) or bidirectional (inout).

Semantics

A FlowProperty defines the type and the direction of a single element carried in a dataflow. It can relate either to a Classifier, a Signal, a PrimitiveType or a DataType. Depending on its direction attribute, it may represent a flow element entering and/or leaving a component through a flow port. The type and direction of a flow property are used to evaluate whether flow ports are type-compatible. A flow property typed by a Signal, specifying an incoming flow direction, maps to a Reception of the signal. A flow property typed by a Signal, specifying an outgoing flow direction, declares the ability for the port to relay the signal over connectors. This concept matches the FlowProperty concept defined in SysML.

F.6.9 FlowSpecification

A FlowSpecification provides a way to define structured elements that a non-atomic flow port may relay. It defines a series of flow properties with their own types and flow direction.

Associations

- property: FlowProperty [*] flow properties owned by the flow specification.

Semantics

A FlowSpecification provides a way to define structured elements that a non-atomic flow port may relay. It defines a series of flow properties with their own types and flow direction. This concept matches the FlowSpecification concept defined in SysML.

Constraints

[1] A flow specification owns only properties, it cannot own operation or reception.

F.6.10 InteractionPort (abstract)

An InteractionPort specifies an interaction point on a structured component. It factorizes the common structural properties of ports used in the General Component Model.

Generalizations

- Property (from MARTE::CoreElements::Foundations).

Associations

- owner: Component [1] component owning the port.

Semantics

An InteractionPort is an abstract class that specifies an interaction point on a structured component. It factorizes the common structural properties of ports used in the General Component Model.

F.6.11 InvocationAction (abstract)

An InvocationAction defines common invocation mechanisms used in the General Component Model.

Generalizations

- Action (from MARTE::CoreElements::Causality::CommonBehavior).

Attributes

- onPort: Port[1] port on which the invocation action is triggered.

Semantics

An Invocation action is an abstract class that factorizes invocation mechanisms common to message-, and flow-based communication.

F.6.12 MessagePort

A MessagePort is a concrete kind of Port used for message-based communications between components. It relays only services calls and/or signals. A MessagePort is identified by the services it provides/requires, as well as the type of signal it produces/consumes.

Generalizations

- Port (from MARTE::CoreElements::GeneralComponent).

Attributes

- isAtomic: Boolean [1] = false indicates whether the port is atomic (i.e. it is typed by a signal).
- kind: BFeatureKind [0..1] kind of the port when the later is not atomic.
- IsConjugated: Boolean [0..1]

Associations

- None

Semantics

A MessagePort supports message-based communications: it assumes a request/reply communication schema between components. In compliance with UML, a service is considered as provided if the message port is typed by an interface that defines the service. A service is considered as required if the port is typed by a class that makes use of an interface, in which is defined the service. Additionally, the General Component Model provides the ability to directly declare provided and required services on a message port, through the "provided" and "required" associations. The "kind" attribute indicates whether the port has provided or required services or signal receptions.

Constraints

[1] if isAtomic is false then the property direction is not applicable.

self.isAtomic = false implies direction->size() = 0

F.6.13 ServiceCallAction

A ServiceCallAction is an action that invokes a service provided by other connected components and may receive a return value.

Generalizations

- InvocationAction (from MARTE::CoreElements::GeneralComponent).

Associations

- serviceToCall: ServiceFeature [1]service to invoke.

Semantics

This concept matches the CallAction classifier defined in UML.

F.6.14 ServiceFeature

A Service is a behavior that a component provides or requires to/from other components. A service is used in message-based communication when a component invokes a behavior through a service call and expects a reply to be provided.

Associations

- owner: ServiceSpecification [*]

Semantics

A Service represents an externally visible behavior owned by a component. A service is used in message-based communication as a contract between components: the owner component provides a service through one of its ports to other components, which require the service. Using a request/reply communication schema, a component that requires a service may invoke it through a service call. The client component expects then a reply to be provided by the service provider.

F.6.15 ServicePort

Generalisations

Associations

- specification: ServiceSpecification [*]

Semantics

F.6.16 ServiceSpecification

Associations

- service: Service Feature [*]

Semantics

F.6.17 SignalFeature

A Signal is used to characterize unidirectional, loose-coupled, communications between components. A component may produce or consume a signal. If so, it needs to declare incoming or outgoing signals on its ports. A signal may define attributes that represent the piece of information transmitted from a component to another one.

Attributes

- direction: DirectionKind [0..1]

Associations

- owner: SignalSpecification [*]

Semantics

Signals support the concept of loose-coupled communication between components. A component that sends a signal does not expect a reply from a receiver. The receiver component consumes the signal, provided it knows how to handle it, and triggers a related behavior in an asynchronous way. Signals provide a way to notify components of events they may want to handle. This concept matches the Signal classifier defined in UML, as well as the CCM events.

F.6.18 SignalPort

Generalisations

Associations

- specification: SignalSpecification [*]

Semantics

F.6.19 SignalSpecification

Associations

- signal: SignalFeature [*]

Semantics

F.6.20 StandardPort

A StandardPort is a concrete kind of Port used for communications based on a request/reply paradigm. A standard port defines a series of provided and required interfaces, which define operations. An interface is considered as provided if the standard port is typed by this interface or by a class that implements this interface. An interface is considered as required if the the standard port is typed by an a class that makes use of the interface.

Generalisations

- InteractionPort.

Semantics

This concept matches the CompositeStructures ::InternalStructures ::Port classifier defined in UML.

F.6.21 StructuredComponent

A StructuredComponent is a self-contained entity of a system, which encapsulates structured data and behavior. StructuredComponents may interact directly or through their ports, preventing access to their internal features by other means. The structure of a component is defined in term of assembly parts, which type refers to external structured components, and connectors. Parts may be linked using connectors provided related components or ports are type-compatible.

Generalizations

- BehavioedClassifier (from MARTE::CoreElements::Causality::CommonBehavior).

Associations

- ownedConnectors: Connector [*] connectors owned by the component.
- ownedPorts: Port [*] {subsets ownedProperties} ports owned by the component.
- parts: Property [*] parts owned by the component.

Attributes

- None

Semantics

This concept matches the CompositeStructures::InternalStructures::StructuredClassifier classifier defined in UML. As in UML, the "parts" association role is derived, based on a selection of properties with a "isComposite" attribute set to true.

F.7 HLAM

F.7.1 CallConcurrencyKind

CallConcurrencyKind is an enumeration, which literals specify the concurrency policy applied to a protected passive unit.

Literals

- sequential a schedulable resource at a time can access a feature of a protected passive unit.
- guarded a schedulable resource at a time can access a feature of a protected passive unit while concurrent ones are suspended.
- concurrent multiple schedulable resources at a time can access a protected passive unit.

F.7.2 CompResPolicy

CompResPolicy is used to specify the scheduling policy of resources managed by an incoming message queue.

Attributes

- policy: SchedulingPolicyKind [0..1] scheduling policy of resources managed by a message queue.

Semantics

CompResPolicy reifies a scheduling policy defined as a literal of the SchedulingPolicyKind enumeration in the General Resource Model (GRM). It is used along with the redefined association: schedulingPolicy to specify the scheduling policy of computing resources for an incoming message queue.

F.7.3 ConcurrencyKind

ConcurrencyKind is an enumeration, which literals specify the kind of concurrency policy of a behavioral feature.

Literals

- reader a behavioral feature execution has no side effects (i.e. it does not modify the state of the object or the values of its properties).
- writer a behavioral feature execution may have side effects.
- parallel a behavioral feature execution may be done in parallel of any kind of service.

F.7.4 ExecutionKind

ExecutionKind is an enumeration, which literals specify the kind of execution of a behavioral feature.

Literals

- deferred the event occurrence matching the service invocation is stored in the queue of the behavior attached to the object.
- remoteImmediate the execution is performed immediately with a computing resource of the calling object.
- localImmediate the execution is performed immediately with a computing resource of the called object.

F.7.5 InMsgQueue

An incoming message queue plays the role of broker for schedulable resources owned by a real-time unit. It stores incoming messages before schedulable resources can process them. A schedulable resource can be assigned to handle a message when its gets available, based on a scheduling policy.

Generalizations

- ResourceBroker (from MARTE::GRM::ResourceTypes).
- StorageResource (from MARTE::GRM::ResourceTypes).

Attributes

- queueSchedPolicy: SchedulingPolicyKind scheduling policy used to manage a queue.
- queueSize: Integer size of a queue, in the case of a size-limited queue.
- msgMaxSize: Integer maximum size of a message stored in a queue.

Associations

- exeRes: SchedulableResource [*] {subsets managedResource}
schedulable resources brokered by the queue.
- rOcc: ReceiveOccurrence [*]
occurrences of message reception.
- schedulingPolicy: CompResPolicy [1..*] {subset accCtrlPolicy}
scheduling policies used for controlling access to schedulable resources.

Semantics

An incoming message queue stores incoming messages before they can be executed by a schedulable resource owned by a real-time unit. Messages are handled in the queue based on a defined scheduling policy. The size of the message queue may be either infinite or limited.

F.7.6 PoolMgtPolicy

PoolMgtPolicy is an enumeration, which literals specify the kind of pool management policy used for schedulable resources of a real-time unit.

Literals

- `infiniteWait`
If the pool is empty then the real-time unit waits indefinitely until a computing resource is released.
- `timedWait`
If the pool is empty then the real-time unit waits for a bounded time until a computing resource is released. An exception is raised if no computing resource is available by the end of the waiting time.
- `create` If the pool is empty then the real-time unit creates a new computing resource and adds it to the pool.
- `exception` If the pool is empty then the real-time unit raises an exception.
- `Other` Other pool management policy.

F.7.7 PpUnit

A protected passive unit is used to represent shared information among real-time units. It does not own any schedulable resource. Meanwhile, it provides protection mechanisms to support concurrent accesses by multiple real-time units.

Generalizations

- `BehavedClassifier` (from `MARTE::CoreElements::Causality::CommonBehavior`).
- `SynchResource` (from `MARTE::CoreElements::Causality::CommonBehavior`).

Attributes

- `concPolicy`: `CallConcurrencyKind` [0..1] concurrency policy applied to a protected passive unit.

Associations

- `behaviors`: `RtBehavior` [*] behaviors owned by a protected passive unit.
- `services`: `RtService` [*] {subsets `pServices`} services owned by a protected passive unit.

Semantics

A protected passive unit is used by real-time units to carry information, while providing protection mechanisms against concurrent accesses. It does not own any computing resource but defines behaviours and services. A protected passive unit may specify its concurrency policy globally, using its `concPolicy` attribute. It may also specify its concurrency policy locally through the `concPolicy` attribute of the `RtService` classifier. The execution kind of a protected passive unit is either `immediateRemote` or `deferred`. In both cases, the computing resource of the real-time unit invoking the service of the protected passive unit is used.

Constraints

[1] The execution kind of a protected passive unit is either `immediateRemote` or `deferred`.

F.7.8 RtAction

A real-time action is an action that may specify real-time characteristics by the means of a real-time feature. It may also define a synchronization kind and a message size, both related to the execution of the action.

Generalizations

- Action (from MARTE::CoreElements::Causality::CommonBehavior).

Attributes

- syncKind: SynchronizationKind [0..1] kind of synchronization used when the action executes.
- isAtomic: Boolean [1] = false when true, implies that the Action executes as one indivisible unit, non-interleaved with other actions.
- msgSize: NFP_DataSize [0..1] size of a message generated when the action is executed.

Associations

- pRTF: RealTimeFeature [0..1] real-time feature related to a RtAction.

Semantics

An RtAction is an Action specialized with the additional aforementioned attributes of "real-time" constraints.

F.7.9 RtBehavior

A real-time behavior is a kind of behavior owned by a real-time unit or a protected passive unit. It owns a message queue used to store the messages received by the behavior owner. Messages are extracted from the queue and processed based on a priority criterion (e.g. priority, deadline) and a given scheduling policy.

Generalization

- Behavior (from MARTE::CoreElements::Causality::CommonBehavior).

Associations

- queue: InMsgQueue [1] incoming message queue owned by a behavior.

Semantics

A real-time behavior implicitly owns a queue to store the messages received by the real-time unit. If its owning unit is a real-time unit, a schedulable resource, as soon as it gets available, may be assigned to handle a message. Otherwise, messages received by the behavior owner are stored in the message queue. A real-time behavior may be also owned by a protected passive unit.

F.7.10 RealTimeFeature

A real-time feature defines special characteristics that can be attached to a real-time service, a real-time action, a message or a signal.

Attributes

- utility: UtilityType [0..1] specifies an "importance" feature. The UtilityType data type is defined in the MARTE_Library. This type is abstract and it is to the user to define its own specialized utility type according to its needs.
- occKind: ArrivalPattern [0..1]

arrival pattern (e.g. periodic, aperiodic).

- tRef: TimedInstantObservation [0..1]
time reference used by the other relative timing attributes.
- relDI: NFP_Duration [0..1]
relative deadline (with respect to the time reference).
- absDI: NFP_DateTime [0..1]
absolute deadline.
- boundDI: NFP_Duration [0..1]
relative deadline.
- rdTime: NFP_Duration [0..1]
minimal ready-time.
- miss: NFP_Percentage [0..1]
percentage of tolerance for missing the deadline.
- priority: NFP_Integer
priority.

Semantics

A real-time feature is used to define special real-time characteristics a real-time service, a real-time action, a message or a signal.

F.7.11 RtService

An RtService can specify the real-time features described by its attributes.

Generalization

- Service (from MARTE::GRM::ResourceCore)

Attributes

- concPolicy: ConcurrencyKind [1] concurrency policy used for the real-time service.
- exeKind: ExecutionKind [1] execution policy used for the real-time service.
- isAtomic: Boolean [1] = false when true, implies that the RtService executes as one indivisible unit, non-interleaved with other RtServices.
- syncKind: SynchronizationKind [1] synchronization policy used for the real-time service.

Associations

- pRTF: RealTimeFeature [0..1] real-time feature that can be attached to a real-time service.

Semantics

An RtService is a Service specialized with the additional aforementioned attributes of "real-time" constraints. These attributes apply for all the invocations of the RtService.

F.7.12 RtUnit

A real-time unit is similar to the active object of UML but with a more detailed semantics description.

Generalizations

- BehavioredClassifier (from MARTE::CoreElements::Causality::CommonBehavior).
- ConcurrencyResource (from MARTE::CoreElements::Causality::CommonBehavior).
- ResourceManager (from MARTE::GRM::ResourceTypes).

Attributes

- isDynamic: Boolean [0..1]
if true, it denotes that the real-time unit creates dynamically the resource required to execute its services. Otherwise, the real-time unit owns a pool of schedulable resources to execute its services.
- isMain: Boolean [0..1]
indicates whether the real-time unit is the main application unit.
- MemorySize: NFP_DataSize [0..1]
amount of static memory requires for each instance of the real-time unit to be placed in an application.
- poolSize: Integer [0..1]
size of the schedulable resource pool of a real-time unit.
- poolPolicy: PoolMgtPolicy [0..1]
pool management policy of a RtUnit.
- poolWaitingTime: NFP_Duration [0..1]
maximal time that a real-time unit waits for a schedulable resource to be released. This attribute is applicable in the case of a pool management policy set to "timedWait".

Associations

- behaviors: RtBehavior [*] behaviors owned by a RtUnit.
- exeRes: ComputingResource [*] computing resources owned by a real-time unit.
- main: RtService [0..1] {subsets pServices} service used as the application entry point, in case of the main unit.
- operationalModes: RtBehavior [0..1] behavior used to describe unit configurations.
- services: RtServices [*] {subsets pServices} services owned by a RtUnit.

Semantics

A real-time unit is similar to the active object of UML but with a more detailed semantics description. It owns at least one schedulable resource but can also have several ones. If its dynamic attribute is set to true, the resources are created dynamically when required. In the other case, the real-time unit has a pool of scheduling resources. When no schedulable resource are available in the possible, the real-time unit may either wait indefinitely for a resource to be released, or wait only a given amount of time (specified by its poolWaitingTime attribute), or dynamically increase its pool of thread to adapt to the demand, or generate an exception. A real-time unit may own behaviors, for which are defined a message queue used to store incoming messages. The size of this message queue may be infinite or limited. In the latter case, the

queue size is specified by its `maxSize` attribute. In addition, a real-time unit owns a specific behavior, called operational mode. This behavior takes usually the form of a state-based behavior where states represent a configuration of the real-time unit and transition denotes reconfigurations of the unit.

Constraints

[1] A main real-time unit shall specify a main service.

`self.isMain=true` implies `self.main->size() = 1`

F.7.13 SynchronisationKind

`SynchronisationKind` is an enumeration, which literals specify the synchronization mechanism used for real-time actions and services.

Literals

- `synchronous` the client waits for the end of the invoked behavior before continuing its own execution.
- `asynchronous` the client does not wait for the end of the invoked behavior to continue its own execution.
- `delayedSynchronous` the client continues to execute and will synchronize later when the invoked behavior returns a value.
- `rendezVous` the behavior waits for the client to start executing.
- `Other` other synchronization policy.

F.8 DRM::SRM

F.8.1 Alarm (from SRM::SW_Concurrency)

Generalizations

- `InterruptResource` (from `SRM::SW_Concurrency`).

Associations

- `timers: TimerMechanism` (from `GRM::ResourceType`) [0..1]
timer which raises the signal to execute the entry-point of the alarm resource.

Attributes

- `isWatchdog: Boolean` [0..1] if true the alarm is a watchdog.

Semantics

Alarm resource provides executing context to a user routine, which must be connected to a timer invoked after a one-shot or periodically. A particular alarm is the watchdog. If the application doesn't succeed in resetting the watchdog, that mean that the system is not functioning properly and the alarm occurs, forcing application to execute the watchdog entry point or to reset the processor.

F.8.2 AccessPolicyKind (from SRM::SW_Brokering)

The AccessPolicyKind enumerates common policy to access a resource.

Literals

- Read read access only.
- ReadWrite read and write access allowed.
- Write write access only.
- Undef undefined policy.
- Other other user's specific policy.

F.8.3 ConcurrentAccessProtocolKind (from SRM::SW_Interaction)

The ConcurrentAccessProtocolKind enumerates common protocol to access mutually a shared resource.

Literals

- NoPreemption lock the concurrency to avoid preemption when a resource is accessing a shared variable.
- PCP priority Ceiling protocol.
- PIP priority Inheritance Protocol.
- Undef undefined policy.
- Other other user's specific policy.

F.8.4 DeviceBroker (from SRM::SW_Brokering)

Generalizations

- ResourceBroker (from GRM::ResourceManagement).
- SwResource (from SRM::SW_ResourceCore).

Associations

- closeServices: GRM::ResourceCore::ResourceService [0..*]
services which make the hardware device unavailable from software resources.
- controlServices: GRM::ResourceCore::ResourceService [0..*]
services which initialize and broke the device.
- devices: GRM::ResourceType::DeviceResource [0..*]
Hardware device brokered by the driver.
- openServices: GRM::ResourceCore::ResourceService [0..*]
services which establish the connection between a device and the resource. This service makes available the device to software resources.

- readServices: GRM::ResourceCore::ResourceService [0..*]
services which read data from the device.
- writeServices: GRM::ResourceCore::ResourceService [0..*]
services which write data to the device.

Attributes

- accessPolicy : AccessPolicyKind [0..1] access policy to the device (read, write ...).
- isBuffered: Boolean[0..1] specifies if data is read and written in large chunks and buffered privately.

Semantics

A DeviceBroker (i.e. driver) interfaces peripheral devices to the software execution support. It makes devices accessible for software. It initializes the software interface to access the device (i.e. a driver). Commonly, deviceBroker resources are based on file mechanisms.

F.8.5 EntryPoint (from SRM::SW_Concurrency)

Generalizations

- Allocation (from Allocations).

Attributes

- isReentrant: Boolean [0..1]
specifies if a single copy of the routine instructions in memory can be shared by multiple concurrent resource. If true, instructions describe in the routine could be called from multiple concurrent resource contexts simultaneously without conflict.
- routine: Behavior [1]
routine which has to be executed in the context of the software computing resource.

Semantics

The EntryPoint supply the routine (i.e. operations) executed in the context of the SwConcurrentResource. At creations of concurrent resources, users are usually invited to define as parameter a sequence of action to be executed in the context provided by the concurrent resource. For example, the POSIX standard provides a computing resource creation service named "pthread_create" where users define the entry point of that resource by the parameter "start_routine".

F.8.6 InterruptResource (from SRM::SW_Concurrency)

Generalizations

- SwConcurrentResource (from SRM::SW_Concurrency).

Associations

- isr : EntryPoint [0..*]
interrupt service requests (i.e. entryPoint).
- routineConnect: GRM::ResourceCore::ResourceService [0..*]

services which connect the routine to the interrupt vector.

- routineDisconnect: GRM::ResourceCore::ResourceService [0..*]
services which disconnect the routine to the interrupt vector.

Attributes

- kind: InterruptKind [0..1]
kind of interrupt.
- isMaskable: Boolean [0..1]
interrupts may be maskable. Only few critical signals raise non maskable interrupts. The control processor unit (CPU) always recognizes those. Maskable interrupts can be in two states: unmasked (i.e. recognized by the CPU) or masked (i.e. ignored by the control unit). For example, a schedulable resource can explicitly mask maskable interrupts to avoid its pre-emption in some code sections.
- maskElements: CoreElements::Foundations::ModelElement [0..*]
elements which map the semantics of the interrupt mask.
- vectorElements: CoreElements::Foundations::ModelElement [0..*]
elements which map the semantics of the interrupt vector.

Semantics

InterruptResource define an executing context to execute user-delivered routines (i.e. entry point) further to hardware or software asynchronous signals. Exceptions are software asynchronous signals. Exceptions can either be "Processor-detected" exceptions when the CPU detects an anomalous condition while executing an instruction or "Programmed" exceptions (also called software interrupts) when they occur at the request of the programmer. Some example of "Processor-detected" exceptions are faults (divide error, device not ready), traps (breakpoints, debug) and aborts (double fault).

F.8.7 InterruptKind (from SRM::SW_Concurrency)

The InterruptKind enumerates different kind of interrupt.

Literals

- HardwareInterrupt
the interrupt source is an hardware one.
- ProcessorDetectedException
software interrupts produced by the CPU control unit while it detects an anomalous condition in executing an instruction. Some examples of "Processor-detected" exceptions are faults (divide error, device not ready) and aborts (double fault).
- ProgrammedException
software interrupts produced by an explicit request of the programmer. Some examples of "ProgrammedException" exceptions are traps (breakpoints, debug).
- Undef
undefined mechanism.
- Other:
others mechanisms.

F.8.8 MemoryBroker (from SRM::SW_Brokering)

Generalizations

- ResourceBroker (from GRM::ResourceManagement).
- SwResource (from SRM::SW_ResourceCore).

Associations

- memories: GRM::ResourceType::StorageResource [0..*]
hardware devices brokered by the driver.
- lockServices: GRM::ResourceCore::ResourceService [0..*]
services which lock the paging or the swapping.
- mapServices: GRM::ResourceCore::ResourceService [0..*]
services which map real memory onto the virtual address ranges used in memory partition.
- unlockServices: GRM::ResourceCore::ResourceService [0..*]
services which unlock the paging or the swapping.
- unMapServices: GRM::ResourceCore::ResourceService [0..*]
services which unmap real memory onto the virtual address ranges used in memory partition.

Attributes

- accessPolicy : AccessPolicyKind [0..1]
access policy to the memory (read, write ...).
- memoryBlockAddressElements: CoreElements::Foundations::ModelElement [0..*]
elements which maps the semantic of the memory block address.
- memoryBlockSizeElements: CoreElements::Foundations::ModelElement [0..*]
elements which map the semantic of the a memory block size.

Semantics

MemoryBroker resources provide primarily services to manage the memory allocation, the memory protection and the memory access.

F.8.9 MemoryPartition (from SRM::SW_Concurrency)

Generalizations

- SwResource (from SRM::SW_ResourceCore).

Associations

- concurrentResources: SRM::SW_Concurrency::SwConcurrentResource [0..*]
concurrent resources executing in that address space.
- exitServices: GRM::ResourceCore::ResourceService [0..*]
services which release address spaces.

- forkServices: GRM::ResourceCore::ResourceService [0..*]
services which spawn a new address space.
- memorySpaces: GRM::ResourceType::StorageResource [0..*]
parts of the memory linked to this address space.

Semantics

MemoryPartition represents a virtual address space. It insures that each concurrent resource associated to a specific memory partition can only access its own memory space.

F.8.10 MessageComResource (from SRM::SW_Interaction)

Generalizations

- SwCommunicationResource (from SRM ::SW_Interaction).

Associations

- receiveServices: GRM::ResourceCore::ResourceService [0..*] services which get a message.
- sendServices: GRM::ResourceCore::ResourceService [0..*] services which set a message.

Attributes

- isFixedMessageSize : Boolean [0..1]
specifies whether all messages managed by the resource have the same size.
- mechanism: MessageResourceKind [0..1]
specifies the kind of mechanism use to exchange message
- messageQueueCapacityElements: CoreElements::Foundations::ModelElement [0..1]
upper limit of message number allowed in a queue.
- messageQueuePolicy: QueuePolicyKind [0..1]
algorithm to manage the outgoing message queue.
- messageSizeElements: CoreElements::Foundations::ModelElement [0..*]
parameters used in message exchange services to defines the size of the message.

Semantics

MessagingComResource defines communication resource to exchange message. Real-time platforms provide several communication mechanisms to exchange data in a concurrent resource context. Commonly, users can manipulate message queues, pipes, blackboards, buffer, etc.

F.8.11 MessageResourceKind (from SRM::SW_Interaction)

The MessageResourceKind enumerates common mechanisms provide by platform to exchange data.

Literals

- Blackboard defines a one message buffer.

- MessageQueue defines a multiple message buffer.
- Pipe defines POSIX Pipe mechanism, which allows data flow among separate memory partition.
- Undef undefined mechanism.
- Other other mechanisms.

F.8.12 MutualExclusionResourceKind (from SRM::SW_Interaction)

The MutualExclusionResourceKind enumerates common mechanisms provide by platform to synchronize resource.

Literals

- BooleanSemaphore binary semaphore. It is a flag available or unavailable. There is no proprietary purpose. Anybody can give the semaphore even if it does not take it.
- CountSemaphore counting semaphore for which every time the semaphore is given the count is incremented; every time the semaphore is given the count is decremented.
- Mutex binary semaphore associated with a propriety concept, resource can give the semaphore if and only if the resource takes it.
- Undef undefined mechanisms.
- Other other mechanisms.

F.8.13 NotificationKind (from SRM::SW_Interaction)

The NotificationKind enumerates common policy to access a resource.

Literals

- Bounded each occurrence increments a counter.
- Memorized occurrences are memorized in a buffer.
- Memoryless occurrences are not memorized in a buffer, hence multiple occurrences are lost.
- Undef undefined.
- Other user's specific policy.

F.8.14 NotificationResourceKind (from SRM::SW_Interaction)

The NotificationResourceKind enumerates common mechanisms provide by support to notify occurrence.

Literals

- Barrier barrier mechanism.

- Event event mechanism.
- Undef undefined mechanisms.
- Other other mechanisms.

F.8.15 NotificationResource (from SRM::SW_Interaction)

Generalizations

- SwSynchronizationResource (from SRM::SW_Interaction).

Associations

- clearServices: GRM::ResourceCore::ResourceService [0..*]
services which erase an or several occurrences.
- flushServices: GRM::ResourceCore::ResourceService [0..*]
services to release any resource which wait for an occurrence.
- signalServices: GRM::ResourceCore::ResourceService [0..*]
services which send one or several occurrences.
- waitServices: GRM::ResourceCore::ResourceService [0..*]
services to wait one or several occurrences.

Attributes

- maskElements: CoreElements::Foundations::ModelElement [0..*]
elements which maps the semantic of the mechanism to mask occurrence.
- mechanism: NotificationResourceKind [0..1]
notification mechanism.
- occurrenceCountElements: CoreElements::Foundation::ModelElement [0..*]
elements which maps the semantic of the occurrence number.
- occurrenceKind : NotificationKind [0..1]
kind of notification.

Semantics

NotificationResource supports control flow by notifying the occurrences of conditions to awaiting concurrent resources, such as POSIX Signal, OSEK\VDX Event, ARINC-653 Event... Occurrences can be memorized (i.e. memorized in a buffer), bounded (i.e. each occurrence increments a counter) or memoryless (i.e. not memorized in a buffer, hence multiple occurrences are lost).

F.8.16 QueuePolicyKind (from SRM::SW_Interaction)

The QueuePolicyKind enumerates algorithms provide by resources to order a queue.

Literals

- FIFO the first element put in the queue is the first outgoing.

- LIFO the last element put in the queue is the first outgoing.
- Priority each element is annotated with a priority.
- Undef undefined.
- Other other algorithms.

F.8.17 SharedDataComResource (from SRM::SW_Interaction)

Generalizations

- SwCommunicationResource (from SRM::SW_Interaction).

Associations

- readServices: BehavioalFeature [0..*] services which read the shared data.
- writeServices: BehavioalFeature [0..*] services which write the shared data.

Semantics

SharedDataComResource define specific resource used to share the same area of memory among concurrent resources. They allow concurrent resources to exchange safely information by reading and writing the same area in memory.

F.8.18 SwAccessService (from SRM::SW_ResourceCore)

Generalizations

- ResourceService (from GRM::ResourceCore).

Associations

- accessedElement: CoreElements::Foudations::Property [1] property which is accessed by this service.

Attributes

- isModifier: Boolean specifies if the access modify the resource feature pass by parameters of this service.

Semantics

The services provided by a software resource to access its characteristics: the accessor and the setter.

F.8.19 SwCommunicationResource (abstract) (from SRM::SW_Interaction)

Generalizations

- SwInteractionResource (from SRM::SW_Interaction).
- CommunicationMedia (from GRM::ResourceType).

Semantics

SwCommunicationResource defines data exchange interaction among concurrent resources.

F.8.20 SwConcurrentResource (abstract) (from SRM::SW_Concurrency)

Generalizations

- SwResource (from SRM::SW_ResourceCore).
- ResourceBroker (from GRM::ResourceManagement).
- ConcurrencyResource (from GRM::ResourceType).

Associations

- activateServices: GRM::ResourceCore::ResourceService [0..*]
services which make available a resource to execute. As result, activated resource is ready to compete for the computing resource. In case of interruption, it results in explicitly raised the interrupt (i.e. to set of the interrupt).
- addressSpace: SRM::SW_Concurrency::MemoryPartition [0..1]
address space in which the flow is executed.
- disableConcurrencyServices: GRM::ResourceCore::ResourceService [0..*]
services which lock the competition for a computing resource. As result, any concurrent resource cannot pre-empt the executing resource.
- enableConcurrencyServices: GRM::ResourceCore::ResourceService [0..*]
services which unlock the competition for a computing resource. As result, any concurrent resource can pre-empt the executing resource.
- entryPoints: SRM::SW_Concurrency::EntryPoint [0..*]
entry points of the resource.
- heapSizeElements : ModelElement [0..*]
elements which maps the semantic of the resource heap size in case of dynamic memory allocation.
- resumeServices: ResourceService (from GRM::ResourceCore) [0..*]
services which make available a resource to compete with either ready or pended concurrent resource. Pended resources are blocked due to the unavailability of some other resources. In case of interrupt, resume service is equivalent to an enable service.
- suspendServices: GRM::ResourceCore::ResourceService [0..*]
services which make unavailable a resource to execute. In case of interrupt, suspend service is equivalent to disable service.
- terminateServices: GRM::ResourceCore::ResourceService [0..*]
services which stop definitively resource execution.
- sharedDataResources: SharedDataComResource [0..*]
resources used to share data among computing resources.
- messageResources: MessageComResource [0..*]
resources used to communicate messages among computing resources.
- mutualExclusionResources: SwMutualExclusionResource [0..*]
resources used to synchronize mutual accesses.
- notificationResources: NotificationResource [0..*]

resources used to synchronize computing resources.

Attributes

- activationCapacity: Integer [0..1]
activation number allowed in the system.
- periodElements: CoreElements::Foundations::ModelElement [0..*]
elements which maps the semantic of the resource period in case of a periodic concurrent resource.
- priorityElements: CoreElements::Foundations::ModelElement [0..*]
elements which maps the semantic of the resource priority.
- stackSizeElements: CoreElements::Foundations::ModelElement [0..*]
elements which maps the semantic of the resource stack size.
- type: MARTE_Library::BasicNFP_Types::ArrivalPattern [0..1]
occurrence execution pattern.

Semantics

This resource defines entities, which may execute concurrently sequential part of instructions. SwConcurrentResource is an abstract concept. It provides an executing context to a routine. Typical SwConcurrentResource are schedulableResources, interruptResources and alarms.

F.8.21 SwInteractionResource (abstract) (from SRM::SW_Interaction)

Generalizations

- SwResource (from SRM::SW_ResourceCore).
- ResourceBroker (from GRM::ResourceManagement).
- CommunicationEndPoint (from GRM::ResourceType).

Attributes

- isIntraMemoryPartitionInteraction: Boolean [0..1]
specifies if the mechanism can be accessed from different memory partition (i.e. namespace, address space).
- waitingPolicyElements: CoreElements::Foundation::ModelElement (from) [0..*]
elements by which the communication waiting policy is specified: waiting, ready, waiting with a time out, conditional waiting...
- waitingQueuePolicy: QueuePolicyKind [0..*]
algorithm to manage the resource waiting queue.
- waitingQueueCapacity: Integer [0..1]
number of resources allowed in the waiting queue.

Semantics

InteractionResource is an abstract concept, which denotes generic mechanism to interact among concurrent executing resources. Synchronization and Communication are specific kind of interaction.

F.8.22 SwMutualExclusionResource (from SRM::SW_Interaction)

Generalizations

- SwSynchronizationResource (from SRM::SW_Interaction) on page <PageNumber>.

Associations

- acquireServices: GRM::ResourceCore::ResourceService [0..*]
services which get an access token to a shared information.
- releaseServices: GRM::ResourceCore::ResourceService [0..*]
services which release an access token to a shared information.

Attributes

- accessTokenElements: CoreElements::Foundations::ModelElement (from) [0..*]
elements which maps the semantics of the token used to access a shared information.
- concurrentAccessProtocol: ConcurrentAccessProtocolKind [0..1]
protocol applied in concurrent access.
- mechanism: MutualExclusionResourceKind [0..1]
kind of mechanism use to mutual exclusion synchronization.

Semantics

MutualExclusionResource describe resources commonly used for synchronize access to shared variables. As examples, Boolean semaphore (one token that anybody can release even if it does not get it), mutex (i.e., a Boolean semaphore associated with a propriety concept. Only resource, which gets the mutex, can release it) and counting semaphore (several token may be got and released) are MutualExclusionResource.

F.8.23 SwResource (abstract) (from SRM::SW_ResourceCore)

Generalizations

- Resource (from GRM::ResourceCore).
- ResourceManager (from GRM::ResourceManagement).

Associations

- createServices: GRM::ResourceCore::ResourceService [0..*]
services which allocate and declare the resource to the system.
- deleteServices: GRM::ResourceCore::ResourceService [0..*]
services which free and delete the resource from the system.
- initializeServices: GRM::ResourceCore::ResourceService [0..*]
services which initialize the resource.

Attributes

- identifierElements: CoreElements::Foundations::ModelElement [0..*]
elements which map the semantic of a resource identifier.

- stateElements: CoreElements::Foundations::ModelElement [0..*]
elements which map the semantic of the resource state.
- memorySizeFootprint: CoreElements::Foundations::ModelElement [0..1]
element which maps the memory size footprint of the resource.

Semantics

SwResource model software structural entities provided to the user by execution supports. Commonly, those entities are considered as execution support specific types. By inheritance, SwResource provide to the user a set of ResourceServices and a set of features. Services provided by SwResource gather services provided by software resource to the application (i.e. the work of computing for a ComputingResource for example) and services provided to manage and to broker those resources (i.e. the help to create the software resource for example). A SwResource concept gathers both the resource as such and the manager of that resource.

F.8.24 SwSchedulableResource (from SRM::SW_Concurrency)

Generalizations

- SwConcurrentResource (from SRM::SW_Concurrency).
- SchedulableResource (from GRM::Scheduling).

Associations

- delayServices: GRM::ResourceCore::ResourceService [0..*]
services which delay for a lapse of time the execution. The resource is in a dormant state during this lapse.
- joinServices: GRM::ResourceCore::ResourceService [0..*]
services which suspend the execution of set of concurrent resource until other concurrent resources terminates.
- scheduler: GRM::Scheduling::Scheduler [1]
scheduler which orchestrates the concurrent execution of this kind of resource.
- yieldServices: GRM::ResourceCore::ResourceService [0..*]
services which explicitly relinquish the computing resource. They explicitly ask scheduler to reschedule.

Attributes

- deadlineElements: CoreElements::Foundation::ModelElement [0..*]
elements which map the semantic of a time by which a schedulable resource must have completed a certain activity.
- deadlineTypeElements : CoreElements::Foundation::ModelElement [0..*]
elements which map the semantic of the deadline criticality degree (e.g. soft and hard).
- isPreemptable: boolean [0..1]
specifies if the scheduler can pre-empt that kind of resource.
- isStaticSchedulingFeature: boolean [0..1]
specifies if the scheduling parameters (priority, deadline, timslice ...) are static (i.e. constants define off-line).
- timeSliceElements: CoreElements::Foundation::ModelElement [0..*]

elements which maps the semantic of the timeSlice in case of round robin scheduling

Semantics

SchedulableResource are resources, which executes concurrently to other concurrent resource. The competition for execution among the set of schedulable resource is supervised by a scheduler. In fact, a scheduler interleaves their execution based on a scheduling algorithm. Common SchedulableResource are POSIX Thread, ARINC-653 Process and OSEK/VDX Task... By default, schedulableResources share the same address space but preserve their own contexts (program counter, registers, signal mask, stack, etc).

F.8.25 SwSynchronizationResource (abstract) (from SRM::SW_Interaction)

Generalizations

- SwInteractionResource (from SRM::SW_Interaction).
- SynchronizationResource (from GRM::ResourceType).

Semantics

This resource defines interaction mechanisms to synchronize concurrent execution flow. Real-time platform provide several basics communication mechanisms to synchronize resources. Two usual specializations are the mutual exclusion synchronization and the event synchronization. In using synchronization mechanism, concurrent resources want either to notify or to make sure that they are in specified parts of their code at the same time or not (i.e. mutual exclusion).

F.8.26 SwTimerResource (from SRM::SW_Concurrency)

A SwTimerResource represents an entity that is capable of following and evidencing the pace of time upon demand with a prefixed maximum resolution, at programmable time intervals.

Generalizations

- TimerResource (from MARTE::GRM::ResourceTypes)

Associations

- None

Attributes

- durationElements: ModelElement {redefines GRM::TimerResource::duration}
elements which map the semantic of the interval after which the timer will make evident the elapsed time.

Semantics

A SwTimerResource represents an entity that is capable of following and evidencing the pace of time upon demand with a prefixed maximum resolution, usually with the usage of its reference clock. The SwTimerResource will make evident the arrival of the programmed duration time after the instant of its last starting or resetting.

F.9 DRM::HRM

F.9.1 CacheStructure

CacheStructure is a cache structure tuple type from the HW_Storage package.

Attributes

- nbSets: NFP_Natural specifies the number of sets.
- blockSize: NFP_DataSize specifies the width of a cache block.
- associativity: NFP_Natural specifies the associativity of the cache.

Semantics

The cache is organized under sets of blocks. Associativity value is the number of blocks within one set. Consequently, the cache size is the product of these three attributes.

If the associativity value is 1, cache is direct mapped. Otherwise if the nbSets value is 1, the cache is fully associative.

Detailed description of the cache structure is necessary for performance simulation of HW_Processors.

Example: TLB (Transfer Lookaside Buffer) is typically a fully associative cache.

Constraints

- None

F.9.2 CacheType

CacheType is an enumeration defining the possible cache types.

Literals

- data
- instruction
- unified both data and instruction
- other
- undef

F.9.3 ComponentState

ComponentState is an enumeration defining the possible states for HW_Component.

Literals

- operating
- storage non-operating state

- other
- undef

F.9.4 ConditionType

ConditionType is an enumeration defining the various condition types.

Literals

- temperature
- humidity
- altitude
- vibration
- shock
- other
- undef

F.9.5 Env_Condition

Env_Condition is an environmental condition tupletype from the HW_Layout package.

Attributes

- type: ConditionType specifies the condition type.
- status: ComponentState specifies the required state of the HW_Component.
- description: NFP_String specifies a short description of the environmental condition.
- range: Interval<T->Real specifies the range of possible values.

Semantics

An Env_Condition is characterized by its type (F.9.4), a given state (F.9.3), a short description and an interval of supported values. It is a safety condition applied to an HW_Component in a particular state (e.g. SMP card 14.2.4.3).

The values range of an Env_Condition at storage (non-operating) time is generally wide.

Example: embedded systems are often operating in hostile environments.

Constraints

- ·None

F.9.6 HW_Actuator

Generalizations

- HW_Logical::HW_I/O.

Associations

- None.

Attributes

- None.

Semantics

Actuators are frequently used as mechanisms to introduce motion, or to clamp an object so as to prevent motion. They are devices which transform an input signal (mainly an electrical signal) into motion.

Constraints

- None.

F.9.7 HW_Arbiter

HW_Arbiter is a communication broker concept from the HW_Communication package.

Generalizations

- HW_CommunicationResource.
- ResourceBroker (from MARTE::GRM).

Associations

- controlledMedias: HW_Media [1..*]specifies the controlled connections. Subsets ResourceBroker.brokedResource.

Attributes

- None

Semantics

HW_Arbiter is a communication broker resource. It controls at least one HW_Media and performs arbitration among the multiple masters that are connected to. It could implement any arbitration strategy as a provided HW_ResourceService.

Note that a bus master is a transient role of an HW_EndPoint during a communication transfer. That is a fundamentally different from the HW_Arbiter concept.

Example: an HW_Processor is often arbitrating its system bus and it may temporarily delegate this task to an associated HW_DMA.

Constraints

- None

F.9.8 HW_ASIC

HW_ASIC is a computing resource from the HW_Computing package.

Generalizations

- HW_ComputingResource.

Associations

- None

Attributes

- None

Semantics

HW_ASIC (Application Specific Integrated Circuit) is a computing resource which is customized for a particular use. It offers execution services corresponding to the mapped application.

HW_ASICs are known to be efficient but not flexible. However, notice that many of them are composite and contain processors and memory.

Example: newly video converter ASICs can perform real time compression encoding of a video source image to an optimized format.

Constraints

[1] if a clock frequency is specified, it must belong to op_Frequencies.

F.9.9 HW_Battery

HW_Battery is a power supply resource from the HW_Power package.

Generalizations

- HW_PowerSupply.

Associations

- None

Attributes

- capacity: NFP_Energy quantifies the energy capacity of the HW_Battery.

Semantics

HW_Battery is a non permanent power supply resource. It contains a limited stored energy. Therefore it may restrain the system autonomy.

Example: mobile phones batteries

Constraints

- None

F.9.10 HW_BranchPredictor

HW_BranchPredictor is a branch prediction resource from the HW_Computing package.

Generalizations

- HW_Logical::HW_Resource.

Associations

- None

Attributes

- None

Semantics

An HW_BranchPredictor is the HW_Processor part that determines whether a conditional branch is to be taken or not. Almost all pipelined processors need some form of branch prediction. It may be refined with a prediction behavior model.

Branch prediction description is crucial for processor performance simulation.

Example: Intel Pentium processors apply bimodal prediction.

Constraints

- None

F.9.11 HW_Bridge

HW_Bridge is a particular HW_Media from the HW_Communication package.

Generalizations

- HW_Media.

Associations

- sides: HW_Media [2..*] specifies HW_Medias at the ends of the HW_Bridge.

Attributes

- None

Semantics

The HW_Bridge typically handles communications between two or more HW_Medias. It may realize complex protocol translations.

Like any HW_Media, HW_Bridge has a maximum bandwidth.

Example: PCI-to-ISA Bridge behaves as a PCI target on a PCI bus and as an ISA master on an ISA bus.

Constraints

- None

F.9.12 HW_Bus

HW_Bus is a particular HW_Media from the HW_Communication package.

Generalizations

- HW_Media

Associations

- None

Attributes

- `adressWidth: NFP_DataSize` specifies the supported addressing size. In general, it is a number of bits.
- `wordWidth: NFP_DataSize` specifies the transfer word width.
- `isSynchronous: NFP_Boolean` specifies whether the bus is clocked or not.
- `isSerial: NFP_Boolean` distinguishes serial from parallel buses.

Semantics

HW_Bus denotes a material HW_Media.

It is characterized by its address and word widths, these are functional values, usually different from the wires number of its corresponding HW_Channel seeing that buses may be multiplexed or serial.

Example: ISA (Industry Standard Architecture) is a parallel bus (20-bit address and 8-bit data) operating at 4.77 MHz.

Constraints

[1] Synchronous bus must have a clock frequency.

F.9.13 HW_Cache

HW_Cache is a processing memory from the HW_Storage package.

Generalizations

- HW_ProcesingMemory.

Associations

- None

Attributes

- `level: NFP_Natural [0..1] = 1` specifies the cache level. The default value is 1.

- type: CacheType specifies the type of the cache.
- structure: CacheStructure specifies the structure of the cache.

Semantics

A HW_Cache is an HW_ProcessingMemory where frequently used data can be stored for rapid access. HW_Caches may vary depending on their level, type (F.9.2) and structure (F.9.1).

Example: PowerPC G4 processor owns 32KB L1 instruction and data caches and 512KB L2 on-chip cache.

Constraints

[1] memorySize is derived from structure attribute.

[2] addressSize is greater than the total cache entries number derived from the structure attribute.

F.9.14 HW_Card

HW_Card is a physical entity from the HW_Layout package.

Generalizations

- HW_Component.

Associations

- None

Attributes

- None

Semantics

HW_Card symbolizes a printed circuit board. It is typically a composite HW_Component that comprises other sub components like chips and electrical devices...

Example: A motherboard is an HW_Card.

Constraints

- None

F.9.15 HW_Channel

HW_Channel is a physical entity from the HW_Layout package.

Generalizations

- HW_Component.

Associations

- None

Attributes

- nbWires: NFP_Natural specifies the number of wires within the channel.

Semantics

HW_channel is a physical set of connectors that may transfer data and power between HW_Components.

Example: USB cable is a 4 wires channel.

Constraints

- None

F.9.16 HW_Chip

HW_Chip is a physical entity from the HW_Layout package.

Generalizations

- HW_Component.

Associations

- ownedUnits: HW_Unit [0..*] specifies the sub units of the chip. Subsets HW_Component.subComponents.

Attributes

- technology: NFP_Length specifies the chip manufacturing process.

Semantics

HW_Chip is a physical entity that denotes an integrated circuit. It may be analog or digital and it could contain numerous sub units.

Example: processors, digital memories and ASICs.

Constraints

- None

F.9.17 HW_Clock

HW_Clock is a timing resource from the HW_Timing package.

Generalizations

- HW_TimingResource

Associations

- None

Attributes

- frequency: NFP_Frequency specifies the provided clock frequency.

Semantics

HW_Clock is a fundamental concept. It provides a periodical signal triggering.

Example: a quartz crystal that vibrates at a given frequency.

Constraints

- None

F.9.18 HW_CommunicationResource

HW_CommunicationResource is a high level concept from the HW_Communication package.

Generalizations

- CommunicationResource (from MARTE::GRM).
- HW_Logical::HW_Resource.

Associations

- None

Attributes

- None

Semantics

HW_CommunicationResource is a high level concept which groups all communication actors. It could be a communication media, an arbiter or an end point.

Example: PCI bus (HW_Bus), DMA (HW_Arbiter), a port or an antenna (HW_EndPoint).

Constraints

- None

F.9.19 HW_Component (from HW_Layout)

HW_Component is the main physical entity of the HW_layout package.

Generalizations

- HW_Resource (from HRM::HW_General).

Associations

- subComponents: HW_Component [0..*] the owned physical entities. Subsets HW_Resource.ownedHW.

Attributes

- dimensions: NFP_Length [0..3]
Cartesian dimensions of the HW_Component. It is an ordered attribute.
- /area: NFP_Area
specifies the area of the HW_Component. Derived from dimensions.
- position: Interval<NFP_Natural> [0..2]
position within the enclosing HW_Component. It is an ordered attribute.
- grid: NFP_Natural [0..2]
a rectilinear grid associated to the HW_Component. It is an ordered attribute.
- nbPins: NFP_Natural [0..1]
the number of pins. It is optional.
- weight: NFP_Weight [0..1]
the weight of the HW_Component.
- price: NFP_Price [0..1]
HW_Component price.
- r_Conditions: Env_Condition [*]
required environmental conditions.

Semantics

HW_Component is the main metaclass of the hardware physical model. It is an abstraction of any hardware real entity based on its physical properties. It could be basic or composed of many other subcomponents.

The dimensions attribute represents in order, the length, the width and the height of the HW_Component. It should correspond to the smallest cuboid that encloses the HW_Component. This attribute is optional.

The area attribute is the product of the length and the width of the HW_Component dimensions if specified, elsewhere the default value is 0.

Each composite HW_Component may be considered as a rectilinear grid where subcomponents are located in their corresponding positions. A position is a collection of contiguous rectangles within the grid.

Each HW_Component could also be annotated by its weight, its price and many required environmental conditions (F.9.5).

These characteristics detailed above are crucial for layout, cost and power analysis.

Example: chips (HW_Chip), batteries (HW_Battery)...

Constraints

- [1] area must derive from dimensions.
- [2] subcomponents positions must not exceed the grid.

[3] requiredConditions intervals must be included within the subcomponents corresponding intervals.

F.9.20 HW_Component (from HW_Power)

HW_Component is the main physical entity of the HW_Power package.

Generalizations

- None

Associations

- poweredServices: HW_Physical::HW_ResourceService[0..*]
services of the HW_Component corresponding resource. Redefines HW_Resource.p_HW_Services.
- leakage: HW_PowerDescriptor[0..1]
specifies the component power consumption when it is non-operating.

Attributes

- None

Semantics

HW_Component redefines the same named concept from the merged HW_Layout package. It denotes any hardware physical resource. It may consume power when running provided services and leaks once idle.

Constraints

- None

F.9.21 HW_ComputingResource

HW_ComputingResource is a high level concept from the HW_Computing package.

Generalizations

- ComputingResource (from MARTE::GRM).
- HW_Logical::HW_Resource.

Associations

- None

Attributes

- op_Frequencies : Interval<NFP_Frequency> specifies the range of supported frequencies.

Semantics

HW_ComputingResource is a high level concept that denotes an active execution resource.

Such resources are often clocked and may support a range of operating frequencies.

Example: CPUs (HW_Processor), FPGAs (HW_PLD) are programmable computing resources.

Constraints

[1] if a clock frequency is specified, it must belong to op_Frequencies.

F.9.22 HW_CoolingSupply

HW_CoolingSupply is a cooler component from the HW_Power package.

Generalizations

- HW_Component

Associations

- None

Attributes

- coolingPower: NFP_Power specifies the cooling power.

Semantics

HW_CoolingSupply is a support HW_Component that dissipates heat in order to keep other components within their safe operating temperatures.

Example: fans, heat sinks...

Constraints

- None

F.9.23 HW_Device

HW_Device is a high level concept from the HW_Device package.

Generalizations

- DeviceResource (from MARTE::GRM).
- HW_Logical::HW_Resource.

Associations

- None

Attributes

- None

Semantics

HW_Device is a high level metaclass. It denotes any resource attached to the platform in order to expand its functionality.

Example: sensors, displays (HW_I/O), power regulators (HW_Support)...

Constraints

- None

F.9.24 HW_DMA

HW_DMA (Direct Memory Access) is a memory manager from the HW_Storage package.

Generalizations

- HW_StorageManager.
- HW_Logical::HW_Communication::HW_Arbiter.

Associations

- drivenBy: HW_Logical::HW_Computing::HW_Processor [0..*]processors that control the HW_DMA.

Attributes

- nbChannels: NFP_Naturalthe number of HW_DMA channels.
- transferWidth: NFP_DataSizemaximum supported transfer width.

Semantics

HW_DMA is mainly a memory manager. It allows access to the controlled HW_Memory for reading and/or writing independently of the HW_Processor by taking the control of the communication media.

The attribute nbChannels corresponds to the number of simultaneous transfers that the HW_DMA can handle.

Example: DMA controller is typically part of the motherboard chipset.

Constraints

- None

F.9.25 HW_Drive

HW_Drive is a mass storage memory from the HW_Storage package.

Generalizations

- HW_StorageMemory

Associations

- None

Attributes

- sectorSize : NFP_DataSize specifies the sector size of the HW_Drive.

Semantics

HW_Drive is a permanent storage memory. In some HW_Drives, the storage medium is permanently seated inside. In others, the medium can be replaced.

From a functional point of view, sectorSize attribute corresponds to the smallest physical amount of memory that can be allocated.

Example: 0.85-inch hard disk drives with over 4 GB storage space.

Constraints

- None

F.9.26 HW_EndPoint

HW_EndPoint is a communication interface from the HW_Communication package.

Generalizations

- CommunicationEndPoint (from MARTE::GRM).
- HW_CommunicationResource.

Associations

- connectedTo: HW_Media[0..*] specifies the communication medias that the end point is connected to.

Attributes

- None

Semantics

HW_EndPoint is a generic concept that symbolizes the HW_Resource end points. It is a part of an HW_Resource which serves as an interface to communicate with other HW_Resources through HW_Medias.

Example: ports, pins, slots...

Constraints

- None

F.9.27 HW_I/O

HW_I/O is an input/output device from the HW_Device package.

Generalizations

- HW_Device

Associations

No additional associations.

Attributes

No additional attributes.

Semantics

HW_I/O (Input/Output) is a generic concept. It represents any device that is interacting with its environment.

It may be only an input device like a camera, an output one like a speaker or both like a touch screen.

Example: for embedded systems, HW_I/O is well adapted to symbolize sensors and actuators.

Constraints

- None

F.9.28 HW_ISA

HW_ISA is a part of HW_Processor microarchitecture from the HW_Computing package.

Generalizations

- HW_Logical::HW_Resource.

Associations

No associations.

Attributes

- family: NFP_String specifies the ISA family.
- inst_Width: NFP_DataSize specifies the instruction width.
- type: ISA_Type specifies the ISA type.

Semantics

ISA (Instruction Set Architecture) is a metaclass which models the HW_Processor implemented instruction set architectures. It has a family (x86, ARM, MIPS...), an instruction width and a given type (F.9.50).

The HW_Processor microarchitecture is tightly dependent of the supported ISAs. Therefore HW_ISA metaclass may be refined to a detailed model for HW_Processor simulation or ISS (Instruction Set Simulator) generation.

Example: Intel 386 is a 32-bit CISC architecture from the x86 family.

Constraints

- None

F.9.29 HW_Media

HW_Media is a communication resource from the HW_Communication package.

Generalizations

- CommunicationMedia (from MARTE::GRM).
- HW_CommunicationResource.

Associations

- arbiters: HW_Arbiter [0..*] specifies the HW_Media controllers.

Attributes

- bandwidth: NFP_DataTxRate specifies the transfer bandwidth of the HW_Media.

Semantics

HW_Media is a generic concept. It represents any resource able to transfer data.

It has a theoretical bandwidth, it may be connected to many HW_EndPoints and it may be controlled by many HW_Arbiters.

Example: wire, bus, wireless connection...

Constraints

- None

F.9.30 HW_Memory

HW_Memory is a high level metaclass from the HW_Storage package.

Generalizations

- StorageResource (from MARTE::GRM).
- HW_Logical::HW_Resource.

Associations

- None

Attributes

- memorySize: NFP_DataSize specifies the storage capacity of the HW_Memory.
- addressSize: NFP_DataSize specifies the address width of the HW_Memory.
- timings: Timing[*] specifies timings of the HW_Memory.
- throughput:NFP_DataTxRate specifies the throughput in a memory.

Semantics

HW_memory is the generic metaclass that denotes any form of data storage during some interval of time. It is a protected HW_Resource that may offer read/write HW_ResourceServices.

The timings attribute (F.9.58) is a simple way to annotate detailed timing durations of some HW_Memory services or behaviors. Such details are necessary for performance analysis or simulation.

Example: SDRAMs, hard drives, their buffers...

Constraints

[1] The value of the inherited attribute isprotected is true.

F.9.31 HW_MMU

HW_MMU is a memory manager from the HW_Storage package.

Generalizations

- HW_StorageManager

Associations

- ownedTLBs: HW_Cache[0..*] specifies the owned Translation Lookaside Buffers.

Attributes

- virtualAddrSpace: NFP_DataSize
specifies the managed virtual address space.
- physicalAddrSpace: NFP_DataSize
specifies the managed physical address space.
- memoryProtection: NFP_Boolean
specifies if memory protection is supported.
- /nbEntriesTLB: NFP_Natural
specifies the total number of TLBs entries. Derived from the ownedTLBs association.

Semantics

HW_MMU (Memory Management Unit) is an HW_StorageManager It manages and speeds processor accesses to memory by translating virtual addresses to physical ones via associative caches called Translation Lookaside Buffers (TLB).

In general, TLB entry stores the virtual address of a memory page with its corresponding physical address. It also includes information about the page use that is necessary for memory protection if supported.

Example: all today processors have integrated HW_MMUs.

Constraints

[1] nbEntriesTLB is derived from the ownedTLBs number of entries.

F.9.32 HW_PLD

HW_PLD is a programmable computing resource from the HW_Computing package.

Generalizations

- HW_ComputingResource

Associations

- blocksComputing: HW_ComputingResource[0..*]
specifies owned computing blocks. Subsets HW_Resource.ownedHW.
- blocksRAM : HW_Logical::HW_Storage::HW_RAM[0..*]
specifies the owned HW_RAM memories.

Attributes

- technology: PLD_Technology specifies the HW_PLD technology.
- organization: PLD_Organization specifies the matrix organization of the HW_PLD.
- nbLUTs specifies the number of LUTs within the HW_PLD.
- nbLUT_Inputs specifies the number of inputs of one LUT.
- nbFlipFlops specifies the number of FlipFlops within the HW_PLD.

Semantics

HW_PLD (Programmable Logic Device) is a computing resource in which functions are hardwired. It has a special organization (F.9.53) and it may own several IPs, hardwired or not, such as processors, memories, analogic devices and so on.

The functions are represented by bit streams that are injected into the PLD through interfaces.

The HW_PLD can be dynamically reconfigured, depending on the underlying technology (F.9.54).

Example: an FPGA may contain many processors, arithmetic blocks and some amount of RAM.

Constraints

[1] If a clock frequency is specified, it must belong to op_Frequencies.

F.9.33 HW_Port

HW_Port is a physical entity from the HW_Layout package.

Generalizations

- HW_Component

Associations

- None.

Attributes

- type: PortType specifies the type of the HW_Port whether it is male or female.

Semantics

HW_Port is a particular HW_Component where external equipments are plugged.

Conventionally, HW_Port may be male or female.

Example: USB serial port, DIMM memory slot...

Constraints

- None

F.9.34 HW_PowerDescriptor

HW_PowerDescriptor is the main feature of the HW_Power package.

Generalizations

- None

Associations

- None

Attributes

- consumption: NFP_Power specifies the power consumed.
- dissipation: NFP_Power specifies the power dissipated.

Semantics

HW_PowerDescriptor is a power description feature. It may be attached to an HW_Component and its HW_ResourceServices.

This feature is composed of two instantaneous measures: the power consumption and the heat dissipation. Such properties are crucial for hardware power analysis.

Example: an Intel Pentium processor clocked at 200MHz consumes about 3W when idle but more than 15W under max load.

Constraints

[1] Power consumption is greater than dissipation.

F.9.35 HW_PowerSupply

HW_PowerSupply is a power supplier from the HW_Power package.

Generalizations

- HW_Component

Associations

- None

Attributes

- suppliedPower: NFP_Power specifies the instantaneous supplied power.

Semantics

HW_PowerSupply is a particular HW_Component that supplies power for the hardware platform.

Example: batteries.

Constraints

- None

F.9.36 HW_ProcessingMemory

HW_ProcessingMemory is an abstract concept from the HW_Storage package.

Generalizations

- HW_Memory.

Associations

- None.

Attributes

- repl_Policy: Repl_Policy specifies the replacement policy
- writePolicy: WritePolicy specifies the write policy.

Semantics

HW_ProcessingMemory is an abstract concept that symbolizes fast and volatile working memories. Consequently it has a replacement policy (F.9.56) and a write policy (F.9.59).

Example: caches, RAMs, buffers...

Constraints

- None

F.9.37 HW_Processor

HW_Processor is a computing resource from the HW_Computing package.

Generalizations

- HW_ComputingResource.

Associations

- predictors: HW_BranchPredictor [0..*]
specifies the owned branch prediction units. Subsets HW_Resource.ownedHW.
- caches: HW_Logical::HW_Storage::HW_Cache [0..*]
specifies processor caches. Subsets HW_Resource.ownedHW.
- ownedMMUs: HW_Logical::HW_Storage::HW_MMU [0..*]
specifies the owned Memory Management Units. Subsets HW_Resource.ownedHW.
- ownedISAs: HW_ISA [1..*]
specifies the owned instruction set architectures. Subsets HW_Resource.ownedHW.

Attributes

- /architecture: NFP_DataSize
specifies the instruction width. Derived from ownedISAs.
- mips: NFP_Natural
specifies the throughput of the processor.
- /ipc: NFP_Real
specifies the number of instructions executed each clock cycle. Derived from mips and clock attributes.
- nbCores: NFP_Natural
specifies the number of cores within the HW_Processor.
- nbPipelines: NFP_Natural
specifies the number of pipelines per core.
- nbStages: NFP_Natural
specifies the number of stages per pipeline.
- nbALUs: NFP_Natural
specifies the number of Arithmetic Logic Units within the HW_Processor.
- nbFPUs: NFP_Natural
specifies the number of Floating Point Units within the HW_Processor.

Semantics

HW_Processor is a generic computing resource that symbolizes a processor. HW_Processor contains at least one instruction set architecture (F.9.27), caches (F.9.12) organized under categories and levels, memory management units ([1]) to handle its addressing and branch predictors (F.9.9) to speed pipelined computing.

mips (million instructions per second) and ipc (instructions per clock) attributes characterize the throughput of the HW_Processor, while other attributes concern the microarchitecture.

Example: ARM-7 embedded processor, TI-C6000 VLIW DSP... DSPs are specialized repetitive processors, designed specifically for Digital Signal Processing.

Constraints

[1] If a clock frequency is specified, it must belong to op_Frequencies.

[2] Architecture must derive from the inst_Width of the supportedISAs.

[3] ipc must derive from mips attribute and clock frequency.

F.9.38 HW_RAM

HW_RAM is a processing memory from the HW_Storage package.

Generalizations

- HW_ProcessingMemory

Associations

- None.

Attributes

- organization: MemoryOrganization
specifies the organization of the HW_RAM.
- isSynchronous: NFP_Boolean
specifies whether the HW_RAM is clocked or not.
- isStatic: NFP_Boolean
specifies whether the HW_RAM is static or not.
- isNonVolatile: NFP_Boolean
specifies whether the HW_RAM is volatile or not. Default value is false.

Semantics

HW_RAM (Random Access Memory) is a processing memory that provides fast read/write services. Unlike HW_Drives, it allows data accesses in any order with the same timing.

Each HW_RAM have a special memory organization (F.9.51), which implies its size and its behavior. Such properties coupled with memory timings are necessary for performance simulation.

HW_RAM may be static or dynamic. Dynamic ones needs periodical refreshing (example 14.2.4.2).

Typically HW_RAMs are volatile memories, as they lose their stored data once powered off. Hence, non volatile memories have permanent power supply or an associated HW_ROM.

Example: SDRAM (Synchronous Dynamic RAM) main memory card.

Constraints

[1] memorySize is derived from organization attribute.

[2] addressSize is greater than the number of memory words derived from organization attribute.

[3] synchronous HW_RAM must have a clock frequency.

F.9.39 HW_Resource (from HW_General)

HW_Resource is the main concept of the Hardware Resource Model.

Generalizations

- Resource (from MARTE::GRM)

Associations

- ownedHW: HW_Resource [0..*]
specifies the owned sub-HW_Resources. Subsets Resource.ownedElement.
- p_HW_Services: HW_ResourceService [1..*]
specifies the provided services. Subsets Resource.pServices.
- r_HW_Services: HW_ResourceService [0..*]
specifies the required services.

Attributes

- description: NFP_String [0..1]
specifies a textual description of the HW_Resource.

Semantics

HW_Resource is the most abstract concept of the Hardware Resource Model. It denotes an hardware entity that provides one or many services (HW_ResourceService), and may require some services from other resources.

HW_Resource could be basic or composed of ownedHW sub-resources.

Each HW_Resource can be refined to a logical resource or/and a physical component.

As most of other hardware concepts are inheriting from HW_Resource, they benefit from the same structure.

Example: Every hardware entity is an HW_Resource

Constraints

- None

F.9.40 HW_Resource (from HW_Logical)

HW_Resource is the main concept of the Hardware Logical Model.

Generalizations

- None

Associations

- endPoints: HW_Communication::HW_EndPoint [0..*]
specifies the connection points of the HW_Resource. Subsets ownedHW.
- clock: HW_Timing::HW_Clock [0..1]
specifies an optional frequency clock.

Attributes

- None

Semantics

HW_Resource is the most abstract concept of the Hardware Logical Model. It redefines the HW_Resource from the HW_General to denote a logical entity.

It may have a clock and endpoints.

As most of other hardware logical concepts are inheriting from HW_Resource, they benefit from the same structure.

Constraints

- None

F.9.41 HW_ResourceService (from HW_General)

HW_ResourceService is the main behavior concept of the Hardware Resource Model.

Generalizations

- ResourceService (from MARTE::GRM).

Associations

- None

Attributes

- None

Semantics

HW_ResourceService denotes a service that one HW_Resource provides and others require. It is mainly used within the logical model where HW_Resources are classified depending on their functionalities. Collaborations of resources by means of their services characterize the execution platform.

An HW_ResourceService could be detailed by behavior views.

Example: read/write services of an HW_Memory.

Constraints

- None

F.9.42 HW_ResourceService (from HW_Physical)

HW_ResourceService is the main behavior concept from the hardware Physical Model.

Generalizations

- None

Associations

- consumption: HW_PowerDescriptor [0..1]
specifies the power description of the HW_ResourceService execution.

Attributes

- None

Semantics

HW_ResourceService redefines the same named concept of the HW_General and it denotes a powered HW_Component service. It is associated with a power description which corresponds to the instantaneous consumption of the HW_Component when it is running this service.

Constraints

- None

F.9.43 HW_ROM

HW_ROM is a storage memory from the HW_Storage package.

Generalizations

- HW_StorageMemory

Associations

No additional associations.

Attributes

- type: ROM_Type specifies the HW_ROM type.
- organization: MemoryOrganization specifies the structure of the HW_ROM.

Semantics

HW_ROM for Read-Only Memory is a class of permanent storage memories that provides essentially read services. It can also be rewritable depending of the HW_ROM type (F.9.57).

Each HW_ROM have a special memory organization (F.9.51).

Example: a program ROM of a microcontroller, a mobile phone memory, a BIOS memory...

Constraints

[1] memorySize is derived from organization attribute.

[2] addressSize is greater than the number of memory words derived from organization attribute.

F.9.44 HW_Sensor

Generalizations

- HW_Logical::HW_I/O.

Associations

- None.

Attributes

- None.

Semantics

Sensor is a device which measures a physical quantity and converts it into a signal which can be read by an observer or by an instrument. For example, a mercury thermometer converts the measured temperature into expansion and contraction of a liquid which can be read on a calibrated glass tube. A thermocouple converts temperature to an output voltage which can be read by a voltmeter.

Constraints

- None.

F.9.45 HW_StorageManager

HW_StorageManager is a storage broker concept from the HW_Storage package.

Generalizations

- StorageResource (from MARTE::GRM).
- ResourceBroker (from MARTE::GRM).
- HW_Logical::HW_Resource.

Associations

- managedMemories: HW_Memory[1..*]
specifies the managed memories. Subsets ResourceBroker.brokedResource.

Attributes

- None.

Semantics

HW_StorageManager denotes an abstract memory broker which manages the access or/and the content of some controlled memories.

Example: HW_Processor, HW_MMU, HW_DMA...

Constraints

- None

F.9.46 HW_StorageMemory

HW_StorageMemory is an abstract concept from the HW_Storage package.

Generalizations

- HW_Memory

Associations

- buffer: HW_ProcessingMemory [0..1]
specifies an optional buffer of the HW_StorageMemory.

Attributes

- None

Semantics

HW_StorageMemory in opposition to HW_ProcessingMemory symbolizes permanent and relatively time-consuming storage resources. It may be speed up by associating a cache buffer for frequently accessed data.

Example: Flash memory, HW_Drive...

Constraints

- None

F.9.47 HW_Support

HW_Support is a support device from the HW_Device package.

Generalizations

- HW_Device

Associations

- None

Attributes

- None

Semantics

HW_Support is an abstract concept that denotes a non functional resource from a logical point of view. However support resources are necessary to insure the platform execution.

HW_Power package components are typically support resources.

Example: regulators, batteries, heat sinks...

Constraints

- None

F.9.48 HW_Timer

HW_Timer is a timed counter from the HW_Timing package.

Generalizations

- HW_TimingResource

Associations

- inputClock: HW_Clock [1]
specifies the input clock of the HW_Timer. Redefines HW_Resource.clock.

Attributes

- nbCounters: NFP_Natural specifies the number of counters within the HW_Timer.
- counterWidth: NFP_DataSize specifies the width of one counter.

Semantics

HW_Timer is a set of independent counters clocked periodically with an inputClock.

Each counter may be loaded with an initial value, and then accessed for current ones (example 14.2.4.1). The counter width determines its maximum measurement of cycles. Some HW_Timers allows merge of counters.

Example: most of microcontrollers embed timers.

Constraints

- None

F.9.49 HW_TimingResource

HW_TimingResource is a high-level concept from the HW_Timing package.

Generalizations

- TimingResource (from MARTE::GRM).
- HW_Logical::HW_Resource.

Associations

- None

Attributes

- None

Semantics

HW_TimingResource is an abstract concept that denotes a timing resource.

Example: watchdogs, timers, clocks.

Constraints

- None

F.9.50 HW_Unit

HW_Unit is a physical entity from the HW_Layout package.

Generalizations

- HW_Component

Associations

- subUnits: HW_Unit [0..*] specifies the HW_Unit subunits. Subsets HW_Component.subComponents.

Attributes

- None

Semantics

HW_Unit is an identified area of an integrated circuit. It is a part of an HW_Chip or an enclosing HW_Unit.

Example: the ALU and the FPU are subunits of the EU (Execution Unit) which is in turn a unit of the processor chip.

Constraints

[1] HW_Unit must belong to an HW_Chip or an enclosing HW_Unit.

F.9.51 HW_Watchdog

HW_Watchdog is a particular timer from the HW_Timing package.

Generalizations

- HW_Timer

Associations

- None

Attributes

- None

Semantics

HW_Watchdog is a particular HW_Timer that triggers the system when it ends counting if it is not reset before (example 14.2.4.1).

The reset period is an equation of the counter width and the clock frequency.

Example: most of microcontrollers embed watchdogs.

Constraints

- None

F.9.52 ISA_Type

ISA_Type is an enumeration.

Literals

- RISC Reduced Instruction Set Computer.
- CISC Complex Instruction Set Computer.
- VLIW Very Long Instruction Word.
- SIMD Single Instruction Multiple Data.
- other
- undef

F.9.53 MemoryOrganization

MemoryOrganization is a memory organization tuple type from the HW_Storage package.

Generalizations

- None

Associations

- None

Attributes

- nbRows: NFP_Natural specifies the number of rows.
- nbColumns: NFP_Natural specifies the number of columns.
- nbBanks: NFP_Natural specifies the number of banks.
- wordSize: NFP_DataSize specifies the word width.

Semantics

The memory (HW_RAM and HW_ROM) is organized under banks of rows and columns of words. Consequently, the memory size is the product of all these attributes.

Such detailed description of the memory organization is necessary for performance analysis and HW_Memory simulation.

Example: 64Mo SDRAM could be organized under 4096x256x4x16bit.

Constraints

- None

F.9.54 PLD_Class

PLD_Class is an enumeration.

Literals

- symmetricalArray
- rowBased
- seaOfGates
- hierarchicalPLD
- other
- undef

F.9.55 PLD_Organization

PLD_Organization is the HW_PLD organization tuple type from the HW_Computing package.

Generalizations

- None

Associations

- None

Attributes

- nbRows: NFP_Natural specifies the number of rows.
- nbColumns: NFP_Natural specifies the number of columns.
- class: PLD_Class specifies the HW_PLD Class.

Semantics

An HW_PLD (F.9.31) is organized as a class (F.9.31) with rows and columns.

Constraints

- None

F.9.56 PLD_Technology

PLD_Technology is an enumeration.

Literals

- SRAM
- antifuse
- flash
- other
- undef

F.9.57 PortType

PortType is an enumeration.

Literals

- male
- female
- other
- undef

F.9.58 Repl_Policy

Repl_Policy is an enumeration of the following replacement policies:

- LRU Least Recently Used.
- NFU Not Frequently Used.
- FIFO First In First Out.
- random
- other
- undef

F.9.59 ROM_Type

ROM_Type is an enumeration.

Literals

- maskedROM Not erasable ROM
- EPROM Erasable Programmable ROM (only erasable by exposition to strong ultraviolet light).
- OTP_EPROM One Time Programmable EPROM (inerasable once programmed).
- EEPROM Electrically EPROM (electrically erasable).
- Flash
- other
- undef

F.9.60 Timing

Timing is a memory timing tupletype from the HW_Storage package.

Attributes

- notation: NFP_String specifies the Timing notation.
- description: NFP_String specifies a short description of the Timing.
- value: NFP_Duration specifies the duration value of the Timing.

Semantics

Timing is a generic tupletype that annotates a timing measurement. Memory timings are necessary for performance analysis and accurate simulation.

Example: tCAS of an HW_RAM is the CAS (Column Address Strobe) latency. It is often measured in clock cycles.

Constraints

- None

F.9.61 WritePolicy

WritePolicy is an enumeration.

Literals

- writeBack cache write is not immediately reflected to the backing memory.
- writeThrough writes are immediately mirrored.
- other
- undef

F.10 GQAM

F.10.1 AcquireStep

Generalizations

- Step.

Associations

- acquiredResource: Resource[0..1] resource to be acquired within the step.

Attributes

- resUnits: NFP_Integer [0..1] = 1 units of the resource that are acquired.

Constraints

[1] An AcquireStep may be inserted between execution steps. If an execution step is also an AcquireStep, the resource is acquired at the beginning of the execution step.

F.10.2 AnalysisContext

For each kind of analysis, there is one analysis context in a UML model. This class identifies elements (diagrams) that are of interest for the given analysis. Global parameters of the Context.

Generalizations

- ExpressionContext (from VSL::Expressions).

Associations

- resourcesPlatform: ResourcesPlatform [1..*]
logical containers for the resources used in the behaviour to be analyzed.
- workloadBehaviour: WorkloadBehavior [1]
logical container for the workload model and for the system-level behaviour triggered by it.

Attributes

- contextParams: NFP [*]

Semantics

The contextParams are a set of annotation variables defining global properties of this analysis context. Properties of the workload, behaviour, and resources may be defined as functions of these variables.

F.10.3 BehaviorScenario

A BehaviorScenario defines the behaviour in response to a request event, including the sequence of steps and their use of resources.

Generalizations

- None

Associations

- root: Step [0..1]
root Step to begin the BehaviorScenario.
- Actions: Step [0..1]
set of Steps making up the BehaviorScenario.
- inputStream: RequestEventStream [1..*]
RequestEventStream that initiates it.
- usedResources: Resource [0..*] {ordered}
set of resources used by the scenario

Attributes

- hostDemand: NFP_Duration [0..1]
CPU demand in time units.
- hostDemandOps: NFP_Real [0..1]
CPU demand in operations.
- priority: NFP_Integer [0..1]
- respTime: NFP_Duration [0..1]
end-to-end delay of a part of an operation.
- interOccTime: NFP_Duration [0..1] interval between successive initiations of an operation.
- throughput: NFP_Rate [0..1]
frequency of initiations of an operation.
- utilization: NFP_Real [0..1]
fraction of time an operation is busy (throughput times delay). For a resource, the fraction of time each unit is busy, times the number of units.
- utilizationOnHost: NFP_Real [0..1]
fraction of time the host is busy executing this operation.

Constraints

- [1] The same BehaviorScenario may be associated with one or more RequestEventStreams within the same AnalysisContext.
- [2] hostDemand, hostDemandOps, executionTime, utilization and utilizationOnHost are only defined if all the Steps in the scenario have the same Host.

F.10.4 CommunicationChannel (from GQAM::GQAM_Resources)

A logical communications layer connecting SchedulableResources.

Generalizations

- ConcurrentResource

Associations

- concurrentRes: SchedulableResource [0..1]
the SchedulableResources that communicate by this communications layer.

Attributes

- msgSize: NFP_DataSize [0..1] the size of the message.

F.10.5 CommunicationHost (from GQAM::GQAM_Resources)

A physical communications link.

Generalizations

- CommunicationMedia (from MARTE::GRM).
- ProcessingResource.
- Scheduler (from MARTE::GRM).

Associations

- steps: CommunicationSteps [0..1] CommunicationStep which use this host.

Attributes

- throughput: NFP_Frequency
actual throughput.
- utilization: NFP_Real
utilization of this host.

F.10.6 CommunicationStep

A CommunicationStep is an operation of sending a message over a CommunicationsResource that connects the host of its predecessor Step, to the host of its successor Step.

Generalizations

- Step

Attributes

- msgSize: NFP_DataSize [0..1] size of the message.

F.10.7 EventTrace

A trace of events that can be the source for the request event stream.

Generalizations

- None

Associations

- stream: RequestEventStream [1] indicates the event stream driven by the trace.

Attributes

- None

F.10.8 ExecutionHost

A CPU or other device which executes functional steps.

Generalizations

- ComputingResource (from MARTE::GRM)
- ProcessingResource.
- Scheduler (from MARTE::GRM).

Associations

- steps: ExecutionStep [*]
execution steps that use this host.
- concurrentRes: SchedulableResource [0..1]
schedulable resources (e.g., processes, threads) deployed on this host.

Attributes

- commTxOverhead: NFP_Duration [0..1] host demand for sending messages.
- commRcvOverhead: NFP_Duration [0..1] host demand for receiving messages.
- contextSwitchTime: NFP_Duration [0..1] context switch time.
- clockOverhead: NFP_Duration [0..1]
- schedPriorityRange: NFP_Interval [0..1]
- memorySize: NFP_Integer [0..1]
- utilization: NFP_Real [0..1]

F.10.9 ExecutionStep

An ExecutionStep is a primitive functional operation, modeling a sequential computation on a ProcessingHost.

Generalizations

- Step

Associations:

- concurrentRes: SchedulableResource [0..1] concurrent resource (process, task) in which this Step is executed.
- host: ExecutionHost [0..1] host processor.

Attributes

- None

Constraints

[1] An ExecutionStep cannot be refined to a BehaviorScenario.

[2] The host of an ExecutionStep is the host of its SchedulableResource (process or thread).

F.10.10 LatencyObserver

LatencyObserver specifies a duration observation between startObs and endObs TimedInstantObservations, with a miss ratio assertion (percentage), a utility function, which places a value on the duration, and a jitter constraint. Jitter is the difference between maximum and minimum duration.

Generalizations

- TimedObserver

Associations

- None

Attributes

- latency: NFP_Duration [0..1]
value of the latency.
- missRatio: NFP_Real [0..1]
for soft timing constraints the miss ratio indicates the admitted or actual percentages of "required" latency missed.
- utility: UtilityType [0..1]
provides a value of importance for required timing constraints.
- maxJitter: NFP_Duration [*]
maximum deviation value. It represents a maximum deviation with which a periodic internal event is generated. The output jitter is calculated as the difference between a worst-case latency time and the best-case latency time for the observed event measured from a reference event.

Semantics

LatencyObserver specifies a duration observation between startObs and endObs TimedInstantObservations, with a miss ratio assertion (percentage), a utility function, which places a value on the duration, and a jitter constraint. Jitter is the difference between maximum and minimum duration.

F.10.11 LaxityKind

The LaxityKind is an Enumeration that includes a list of qualifiers specifying the criticality of a given required timing property.

Literals

- hard the required timing specifications have to be met for system behavior correctness.
- soft if the required timing specifications are not met the system behavior is still correct. Further specifications, such as the miss ratio, can be used to specify the limit of timing misses.
- other a user-specific laxity.

F.10.12 PrecedenceRelation

Generalizations

- None

Associations

- predec: Step [*] set of predecessor Steps of the relation
- succes: Step [*] set of successor Steps of the relation

Attributes

- connectorType: ConnectorKind [0..1] type of the precedence relation.

Semantics

The relationship between successive Steps. The precedence relations play the role of the connectors.

F.10.13 ReleaseStep

Generalizations

- Step

Associations

- releasedResource: Resource [0..1] resource released within the step.

Attributes

- resUnits: NFP_Integer [0..1] = 1 unit of the resource that are released.

Constraints

- [1] A ReleaseStep may be inserted between functional steps. If a functional step is also a ReleaseStep, the resource is released at the end of the functional step.
- [2] From Table 15-1. the only meaningful Step attributes are interOccTime and throughput.

F.10.14 RequestEventStream

A stream of events that initiate system-level behaviour. It may be generated in different ways: by a clock, by a stated arrival process (such as Poisson or deterministic), as the output of another subsystem, from an arrival-generating mechanism modeled by a workload generator class, and from a trace.

Associations

- effect: BehaviorScenario [0..1]
behaviour triggered by the event.
- generator: WorkloadGenerator [0..1]
optional mechanism (usually defined by a state machine) that generates the request events.
- trace: EventTrace [0..1]
indicates an event trace file.
- timedEvent: TimedEvent [0..1]
indicates a timed event that generates the event stream.

Attributes

- type: EventStreamKind [0..1]
one of the following enumeration values: {Generator, Pattern, Trace, Timed} which indicates how the request events are obtained.
- pattern: ArrivalPattern [0..1]
if the type value is Pattern, then this attribute of type ArrivalPattern (which is a dataType imported from the model library of Basic::NFPTypes) describes it.

Constraints

- [1] The type attribute determines which source of events defines the stream, and the optional association or attribute for that type must be defined.

F.10.15 RequestedService

Generalizations

- Step

Associations

- None

Attributes

- None

Constaints

- None

F.10.16 ResourcesPlatform

A logical container for the resources used in an analysis context.

Generalizations

- None

Associations

- resources: Resource [*] set of resources contained by this container.

Attributes

- None

Constaints

- None

F.10.17 Step

A Step is a part of a BehaviorScenario, defined in sequence with other actions, and may be a complex Step containing a BehaviorScenario. A loop is defined as a Step with a repetition count; the loop body is a nested BehaviorScenario.

Generalizations

- BehaviorScenario

Associations

- outputRel: PrecedenceRelation [*] successor relation.
- inputRel: Step[*]:PrecedenceRelation [*] predecessor relation.

Attributes

- isAtomic: NFP_Boolean [0..1] if true, the step cannot be decomposed any further.
- blockingTime: NFP_Duration [0..1] delay inserted into the execution of the Step.
- repetitions: NFP_Real [0..1] actual or average number of repetitions of an operation or loop.

- probability: NFP_Real [0..1] probability of the step to be executed (useful for conditional execution).
- priority: NFP_Interval [0..1] step priority.

Attributes

- None

Constraints

[1] There can be more than one end Step in a BehaviorScenario.

[2] hostDemand, hostDemandOps, executionTime, utilization and utilizationOnHost are only defined if all the Steps in the scenario have the same Host.

F.10.18 TimedObserver

TimedObservers are conceptual entities that collect timing requirements and predictions related to a pair of user-defined observed events. In this sense, TimedObserver uses TimedInstantObservations (from the Time sub-profile) to define the observed event in a given behavioral model. Normally the observer expresses constraints on the duration between the two time observations, named startObs and endObs.

Generalizations

- NFP_Constraint (from NFPs::NFP_Annotation)

Associations

- endEvent: Time::TimedRelatedEntities::TimedObservations::TimedInstantObservation [0..1]
observed event to which the timing observer apply.
- startEvent: Time::TimedRelatedEntities::TimedObservations::TimedInstantObservation [0..1]
reference event.

Attributes

- laxity: LaxityKind[0..1]
indicates whether required timing constraints are hard or soft.

Semantics

TimedObservers are conceptual entities that collect timing requirements and predictions related to a pair of user-defined observed events. In this sense, TimedObserver uses TimedInstantObservations (from the Time sub-profile) to define the observed event in a given behavioral model. Normally the observer expresses constraints on the duration between the two time observations, named startObs and endObs. Timing observers are a powerful mechanism to annotate and compare timing constraints against timing predictions provided by analysis tools.

F.10.19 WorkloadBehaviour

Represents a logical container for the analyzed behavior and the workload that triggers it.

Generalizations

- None

Associations

- demand: RequestEventStream [*] indicates the request event streams that are part of this container.
- behavior: BehaviourScenario [*] indicates the set of system behaviors used for analysis.

Attributes

- None

Constraints

- None

F.10.20 WorkloadEvent

Generalizations

- None

Associations

- pattern: ArrivalPattern [*]

Attributes

- None

Constraints

- None

F.10.21 WorkloadGenerator

A mechanism that optionally may serve to create an event stream to trigger a behavior. It may be defined internally by a state machine.

Generalizations

- None

Associations

- behaviour: RequestEventStream [*]

Attributes

- None

Constraints

[1] One generator may trigger several RequestEventStreams, and one Behavior may be triggered by several generators.

F.11 SAM

F.11.1 EndToEndFlow

End-to-end flows describe a unit of processing work in the analyzed system, which contend for use of the processing resources. This is a conceptual entity only, which is represented by its concrete elements: end-to-end stimuli and end-to-end response.

Generalizations

- None

Associations

- endToEndStimuli: RequestEventStream [1..*]
set of request event stream that trigger the processing flow.
- endToEndResponse: BehaviorScenario [1]
end-to-end execution scenario as response to a related set of request event stream.
- Timing: TimedObserver [*]
set of timing requirements or predictions that constrain local fragments or the global end-to-end execution flow.

Attributes

- isSchedulable: NFP_Boolean [0..1]
indicates whether the flow meets all its deadlines.
- schedulabilitySlack: NFP_Real [0..1]
provides a percentage measure by which the (effective) execution time of all the atomic processing units participating in the end-to-end response may be increased while still keeping the end-to-end flow schedulable.
- endToEndTime: NFP_Duration [0..1]
represents the predicted worst completion time latency of the end-to-end response measured from the arrival of the requested event. This applies if only one input end-to-end stimuli exist.
- endToEndDeadline: NFP_Duration [0..1]
represents the required worst completion time latency of the end-to-end response measured from the arrival of the requested event. This applies if only one input end-to-end stimuli exist.

Semantics

End-to-end flows describe a unit of processing work in the analyzed system, which contend for use of the processing resources. As a conceptual entity, end-to-end flow allows to define a set of timing requirements and timing predictions. Timing requirements include deadlines, maximum miss ratios and maximum jitters. Timing predictions are typically provided by analysis tools and include latencies, jitters, and other scheduling metrics.

Constraints

- None

F.11.2 SaAnalysisContext

An analysis context is the root concept to collect relevant quantitative information for performing a specific analysis scenario. Starting with the analysis context and its elements, a tool can follow the links of the model to extract the information that it needs to perform the model analysis. Analysis contexts are also known as real-time situations in the schedulability analysis domain (SaAnalysisContext).

Generalizations

- AnalysisContext (from GQAM)

Associations

- None

Attributes

- isSchedulable: NFP_Boolean

Semantics

In general, SaAnalysisContext is associated with the following two modeling concerns. WorkloadBehavior represents a given load of processing flows triggered by external (e.g., environmental events) or internal (e.g., a timer) stimuli. The processing flows are modeled as a set of related steps that contend for use of processing resources and other shared resources. ResourcesPlatform represents a concrete architecture and capacity of hardware and software processing resources used in the context under consideration.

Constraints

- None

F.11.3 SaStep

A SaStep is a kind of Step that begin and end when decisions about the allocation of system resources are made, as for example when changing its priority.

Generalizations

- Step (from GQAM)

Associations

- sharedRes: SaSharedResource [*] {subsets GRM::ResourceUsage.usedResources}
set of shared resources that will be locked during the execution of this step.

Attributes

- deadline: NFP_Duration [0..1]
maximal time bound on the completion of this particular execution segment that must be met.

- spareCapacity: NFP_Duration [0..1]
amount of execution time that can be added to the step without affecting schedulability.
- schedulabilitySlack: NFP_Real [0..1]
percentage by which the execution time of the step can be increased (positive values) or should be decreased (negative values) in order to reach the schedulability limit.
- preemptedTime: NFP_Duration [0..1]
length of time that the step is preempted, when runnable, to make way for a higher priority step.
- readyTime: NFP_Duration [0..1]
effective release time expressed as the length of time since the beginning of a period; in effect a delay between the time an entity is eligible for execution and the actual beginning of execution.
- nonpreemptionBlocking: NFP_Duration [0..1]
maximum length of time within the context of the current SaStep that a ready SaStep is blocked while lower priority schedulable entities are nonpreemptible.
- selfSuspensionBlocking: NFP_Duration [0..1]
maximum length of time within the context of the current SaStep that a ready SaStep voluntarily yields the Processing Resource.
- numberSelfSuspensions: NFP_Integer [0..1]
maximum number of times an SaStep self suspends during its execution. (MUST be provided if selfSuspensionBlocking is provided.)

Semantics

The ordering of steps follows a predecessor-successor pattern, with the possibility of multiple concurrent successors and predecessors, stemming from concurrent thread joins and forks respectively. The granularity of a step is often a modeling choice that depends on the level of detail that is being considered. A SaStep at one level of abstraction may be decomposed further into a set of finer-grained steps. In this model, steps use the active resource services for execution by means of schedulable resources (e.g., threads, process in execution resources).

Constraints

- None

F.11.4 SaCommunicationStep

A SaCommunicationStep is a kind of step that represents a usage of a communication channel.

Generalizations:

- CommunicationStep (from GQAM)

Attributes:

- deadline: NFP_Duration [0..1]
maximal time bound on the completion of this particular transmission that must be met.
- spareCapacity: NFP_Duration [0..1]
amount of execution time that can be added to the step without affecting schedulability.

- `schedulabilitySlack`: `NFP_Real` [0..1]
percentage by which the execution time of the step can be increased (positive values) or should be decreased (negative values) in order to reach the schedulability limit.

Semantics

A `SaCommunicationStep` is a kind of step that represents a usage of a communication channel.

Constraints

- None

F.11.5 SaExecutionHost

A CPU or other device which executes functional steps. `SaExecutionHost` adds schedulability metrics, interrupt overheads and utilization of scheduling processing.

Generalizations

- `ProcessingResource`

Associations

- `timingRes`: `GRM::ResourceTypes::TimingResources` [*]
execution steps that use this host
- `schedRes`: `GRM::Scheduling::SchedulableResource` [0..1]
schedulable resources (e.g., processes, threads) deployed on this host.
- `sharedResources`: `SharedResource` [0..1]
shared resources owing to this execution host.

Attributes

- `ISRswitchTime`: `NFP_Duration` [0..1]
context switch time of ISR (Interrupt Service Routines) interruptions.
- `ISRpriorityRange`: `NFP_IntegerInterval` [0..1]
range of ISR priorities supported by the platform.
- `isSchedulable`: `NFP_Boolean` [0..1]
indicates whether all the timing constraints defined for the execution host are respected.
- `schedulabilitySlack`: `NFP_Real` [0..1]
percentage by which the execution time of all the steps running in this execution host can be increased (positive values) or should be decreased (negative values) in order to reach the schedulability limit.
- `schedUtilization`: `NFP_Real` [0..1]
total utilization of scheduling services.

Semantics

A CPU or other device which executes functional steps. `SaExecutionHost` adds schedulability metrics, interrupt overheads and utilization of scheduling processing.

F.11.6 SaCommunicationHost

In a communication host (e.g., network and bus), the related schedulable resource element is CommunicationChannel, which may be characterized by concrete scheduling parameters (like the packet size).

Generalizations

- CommunicationHost.

Associations

- commChannels: CommunicationChannels [0..1]
the channels that belong to this host.

Attributes

- isSchedulable: NFP_Boolean [0..1]
indicates whether the transmitted messages meets all its deadlines.
- schedulabilitySlack: NFP_Real [0..1]
provides a percentage measure by which the (effective) transmission time of all the communication steps participating in the host may be increased while still keeping the system schedulable.

Semantics

In a communication host (e.g., network, bus), the related schedulable resource element is CommunicationChannel, which may be characterized by concrete scheduling parameters (like the packet size).

F.11.7 SchedulingObserver

SchedulingObserver provides prediction about scheduling metrics such as overlaps, the maximum number of suspensions caused by shared resources or the blocking time caused by the used shared resources. All these metrics are relative to the interval defined by the reference and observed events.

Generalizations

- TimedObserver

Associations

- None.

Attributes

- suspensions: NFP_Duration [*]
maximum number of suspensions caused by shared resources.
- blockingTime: NFP_Duration [*]
blocking time caused by the used shared resources.
- overlaps: NFP_Duration [*]
in case of soft timing constraints, this indicates how many instances may overlap their execution because of missed deadlines.

Semantics

SchedulingObserver provides prediction about scheduling metrics such as overlaps, the maximum number of suspensions caused by shared resources or the blocking time caused by the used shared resources. All these metrics are relative to the interval defined by the reference and observed events.

F.11.8 SharedResource

Execution Hosts own shared resources as for example I/O devices, DMA channels, critical sections or network adapters. Shared resources are dynamically allocated to schedulable resources by means of an access policy. Common access policies are FIFO, priority ceiling protocol, highest locker, priority queue, and priority inheritance protocol.

Generalizations

- NFP_Constraint (from NFPs::NFP_Annotation).

Associations

- None

Attributes

- capacity: NFP_Integer [0..1]
number of permissible concurrent users, for example using a counting semaphore.
- isPreemptible: NFP_Boolean [0..1]
indicates if the resource can be preempted while it is being used.
- isConsumable: NFP_Boolean [0..1]
indicates that the resource is consumed by use.
- acquisitionTime: NFP_Duration [0..1]
time delay suffered by an action between being granting access to a resource and the availability of the resource.
- releaseTime: NFP_Duration [0..1]
time delay suffered by an action between initiating release of a resource and the action becoming eligible for execution again.

Semantics

Execution Hosts own shared resources as for example I/O devices, DMA channels, critical sections or network adapters. Shared resources are dynamically allocated to schedulable resources by means of an access policy. Common access policies are FIFO, priority ceiling protocol, highest locker, priority queue, and priority inheritance protocol.

F.12 PAM

F.12.1 Perf_Workload_Behavior

A collection of workload and behavior for this AnalysisContext.

Associations

- load:RequestEventStream [1..*] sources of load.
- behavior:BehaviorScenario [1..*] behaviors used in the responses.

F.12.2 Perf_ResourcesPlatform

The collection of resources for this AnalysisContext

Associations

- resource: Resource [0..1] set of resources.

F.12.3 PRequestEventStream

The sequence of initiation events for a behavior.

Generalizations

- RequestEventStream (from GQAM).

Associations

- effect: PBehaviorScenario [*]
behavior triggered by the event stream, specialized for performance analysis.
- generator: PWorkloadGenerator [0..*]
optional mechanism (usually defined by a state machine) that generates the request events, specialized for performance analysis.

Attributes

- workloadKind: PWorkloadKind [1]
- closedPopulation: NFP_Integer [0..1]
- closedExtDelay: NFP_Duration [0..1]
- openIntArrT: NFP_Duration [0..1]
- generator: WorkloadGenerator [0..1]
- traceName: String[0..1]

Constraints

[1] the workloadType attribute governs which other attributes are used to define the workload.

F.12.4 PWorkloadGenerator

A source of system initiation events

Generalization:

- WorkloadGenerator (from GQAM)

Associations

- behaviour: RequestEventStream [*]

Attributes

- population: NFP_Integer [0..1]
number of workload sources, each of which can generate one request at any one time, default = 1.

F.12.5 PStep

A step in a scenario.

Generalizations

- Step (from GQAM).

Associations

- outputRel: PStep [*] set of successor PSteps.
- inputRel: PStep [*] set of predecessor PSteps.
- ownedStep: PStep [*] set of steps in a BehaviorScenario that refines the step.

Attributes

- noSync: Boolean [0..1] = false
flag to indicate that a PStep following a fork in the PBehaviorScenario begins a sub-path which does not join with the other parallel paths.

Semantics

PStep establishes the sequence of the BehaviorScenario. It may be refined to a BehaviorScenario with a separate step for each service. A refined PStep is purely a holder for its refinement sub-BehaviorScenario, and does not have a host or demands of its own. The BehaviorScenario for a refined PStep is defined implicitly as the operand of a CombinedFragment or StructuredActivity.

The probability attribute is required for a PStep immediately following a branch (OR-fork) in the BehaviorScenario (default value is equal probabilities for all paths). On other PSteps it indicates an optional execution (default = 1).

The noSync attribute is meaningful only on a PStep immediately following a fork in the flow of the scenario (par CombinedFragment, asynchronous message, or Fork ActivityNode). It indicates that the subpath following this PStep does not join with the parallel subpaths, but continues until it terminates on its own. It may continue after the join of the other paths. In particular, on an asynchronous message within an operand of a CombinedFragment, it shows that the operand terminates without waiting for the subpath from the asynchronous message. The default value is false.

Constraints

[1] there can be more than one end PStep in a BehaviorScenario

[2] hostDemand, hostDemandOps, executionTime, utilization and utilizationOnHost are only defined if all the Steps in the scenario have the same Host.

F.12.6 PExecutionStep

Generalizations

- PStep (from GQAM).

Associations

- process: PProcess[0..1] process in which this Step is executed.
- host: ProcessingHost[0..1] host processor.
- service: RequestedService [*] set of services requested by this Step.

Attributes

- serviceDemand: ServiceDemand [*]
set of demand for a PRequestedService during the PStep
- behaviorDemand: PBehaviorDemand [*]
set of demand for a behavior described by a scenario, during the PStep.
- extOpDemand: PExtOpDemand [*]
set of demand for an operation defined by an external submodel, during the PStep.

Semantics

A PExecutionStep represents an Operation or an Action. It consists of sequential host execution, possibly interspersed with requests (assumed blocking) to services. At this level of granularity the order of these is unspecified (any order may be assumed). To specify the order, the Step can be refined.

Demands for resources are made in an undetermined order during the PStep. Each demand datatype names its resource, and a quantity of demands:

- hostDemand is implicitly for the ExecutionHost, in units of time,
- serviceDemand and behaviorDemand is for an indicated operation defined by a RequestedService or by a BehaviorScenario, with a quantity in units of operations.
- extOpDemand is for a named operation for which the modeling environment has a known submodel, with a quantity in units of operations.

Constraints

- A PExecutionStep cannot be refined to a BehaviorScenario.
- The host of a PExecutionStep is the host of its process (PProcess).

F.12.7 PResourcePassStep.

Generalizations

- Pstep

Associations

- resource: Resource [1] resource which is passed.

Additional Attributes

- resource: Resource [1] class of resource which is passed.
- resUnits: NFP_Integer [0..1] unit of resource passed, default value 1.

Semantics

Explicit resource passing is required in certain circumstances only. Implicitly, logical resources held by a PBehaviorScenario are passed into sub-scenarios, and to all of the alternative paths at a branch or alternative combination. At a fork, par combination or asynchronous message however the default is that all forked paths hold all the logical resources, and this may need to be over-ridden by PassResource to define which parallel path has which resource. At a subsequent join, the semantics of resource passing are that the union of resources are held by the subsequent behaviour.

Notice that on alternative branches care must be taken in defining the acquiring and releasing resources, to come to the merging of paths with the same set of resources on all branches. Inconsistent resource holdings at a merge are a non-recoverable error in the performance definitions.

Constraints

[1] The units passed cannot exceed those held at that point; if they do, the value is truncated at those held.

F.12.8 PCommunicationStep

Generalizations

- PStep

Associations

- sendHost: ExecutionHost [0..1]
- recvHost: ExecutionHost [0..1]
- process: CommChannel [0..1] logical channel which carries the message.
- host: CommunicationHost [0..1] physical channel which carries the message.

Attributes

- commService: RequestedService [0..1]
- commBehavior: PBehaviorScenario [0..1]
PBehaviorScenario defining the global system behavior to transmit the message.
- commExtOperation: String [0..1]
name of an external operation to convey the message.

Semantics

A `PCommunicationStep` defines a subscenario to convey the message between objects on different nodes, in one of four ways:

- if `commService`, `commBehavior`, and `extOperation` are all null, then the host overhead parameters are used to define a three-Step subscenario (overhead to send, latency across the net, overhead to receive).
- if `commService` is non-null, it identifies a layer operation that has behavior to define the conveyance.
- if `commBehavior` is non-null, it identifies a subscenario which defines the conveyance.
- if `extOperation` is non-null, it identifies an external submodel to be used to determine the delay for conveyance. An example could be a network simulation.

Constraints

[1] Only one of `commService`, `commBehavior`, and `extOperation` may be non -null.

F.12.9 PRequestedService,

A "service", that is an Action of some kind, supplied by an Operation supplied by an Object or Component through its interface. If the Object or Component has a behavior definition for the Operation, the BehaviorScenario for this definition is included in the calling scenario; if not, then a BehaviorScenario can be referenced explicitly. A third shorthand way to define the "service" (as a kind of stub for a full definition) is through its inherited attributes as a `PExecutionStep`.

Generalizations

- `PExecutionStep`

Associations

- `behaviorDef`: BehaviorScenario [0..1] optionally defines the operation.
- `process`: PProcess [0..1] process which executes the component which supplies the service.
- `host` : ExecutionHost [0..1] host of the PProcess.

Semantics

The host and process associations are determined through the configuration information in the UML model, such as the process context of the Object or Component, and its deployment.

Constraints

- [1] If the `behaviorDef` association is present, the BehaviorScenario acts as a refinement to a `PStep`. Only a subset of the inherited attributes are relevant. The relevant subset is the performance measures {`delay`, `executionTime`, `interval`, `throughput`, `utilization`, `utilizationOnHost`, `startTime`, `endTime`}.
- [2] If the `behaviorDef` association is absent, the `PRequestedService` is defined as a stub for the service definition. All the attributes inherited from `PExecutionStep` may be defined; this includes the demand attributes `hostDemand`, `serviceDemand`, `behaviorDemand` and `extOpDemand`.

F.12.10 PBehaviorDemand

A data structure describing a demand for executing a behavior, the type of a behaviorDemand attribute.

Attributes

- requestedBehavior: BehaviorScenario [1] behavior that is demanded.
- opCount: NFP_Real [1] number of operations that are demanded.

F.12.11 PExtOpDemand

A data structure for a demand for an operation which is defined only for the performance modeling environment, and is identified by name. It is the type of an extOpDemand attribute.

Attributes

- extOperation: String [1]
 name of the external operation, meaningful to the performance modeling environment.
- opCount: NFP_Real [1]
 number of operations demands.

F.12.12 PProcess

A designation for a deployed process, a kind of SchedulableResource with performance attributes.

Generalizations

- SchedulableResource (from MARTE::GRM)

Inherited Attributes useful for Performance

- resMult: NFP_Integer [0..1] size of the thread pool of the process

Attributes

- task: String [1] string identifier for the deployed process resource.
- component: ConnectableElement [0..1]
- artifact: Artifact[0..1] deployed artifact for the process which executes this behavior.

Semantics

For performance modeling this represents a process, possibly multithreaded. The capacity gives the level of multithreading, assumed to be static. The component attribute identifies the deployment of the process through the artifact that implements it physically, and thus identifies its host processor.

F.12.13 LogicalResource

Generalizations

- Resource (from MARTE::GRM)

Semantics

A logical resource is any resource which provides the environment for execution, but does not actually execute instructions. Examples include semaphores, mutexes, buffers and locks.

F.13 VSL

F.13.1 BoundedSubtype (from DataTypes)

Generalizations

- Subtype (from DataTypes) on page 567

Attributes

- minValue: String [0..1]
defines a string which specifies that the value space is limited to this value in his lower bound.
- maxValue: String [0..1]
defines a string which specifies that the value space is limited to this value in his upper bound.
- isMinOpen: Boolean [0..1]
defines if minValue is excluded in the bounded value space.
- isMaxOpen: Boolean [0..1]
defines if maxValue is excluded in the bounded value space.

Semantics

BoundedSubtype is a kind of Subtype. BoundedType creates a subtype of any ordered datatype by placing upper and/or lower bounds on the value space (minValue and MaxValue).

F.13.2 ChoiceSpecification (from CompositeValues)

Generalizations

- ValueSpecification (from VSL) on page 568

Associations

- choiceAttribute: VSL::DataTypes::Property [1]
chosen data type' attribute.

Attributes

- /chosenAlternative: String [0..1]
derived String with the name of the chosen data type's attribute.
- value: VSL::ValueSpecification [1]
value specification whose type must conform to the chosen data type's attribute.

Semantics

Choice Specification denotes a value of a choice data type (ChoiceType). It contains the name of one of the attribute members (chosenAlternative), which determines the chosen data type, and a value that conforms to the chosen data type. The derived attribute "chosenAlternative" can be constructed with basis on an explicitly chosen data type. When the chosen data type is undefined in a given choice value specification, the chosen alternative can be deduced from the default alternative attribute of the corresponding choice type.

Generalizations

- CompositeType (from DataTypes) on page 558

Associations

- choiceAttributes: VSL::DataTypes::Property [*]
attribute defines the type, size, uniqueness and order of the alternative members of the choice data type.
- defaultAttribute: VSL::DataTypes::Property [0..1]
attribute defines the default alternative member of the choice data type.

Semantics

Choice Type generates a data type each of whose values is a single value from any of a set of alternative data types. Choice Type combines different types into a single data type. Instances of choice data types belong to only one of the member types. This type is similar to the C union type and the Ada/Pascal "variant-record".

F.13.3 CollectionSpecification (from CompositeValues)

Generalizations

- ValueSpecification (from VSL) on page 568

Associations

- itemValue : VSL::ValueSpecification [*] set of values of a collection.

Semantics

Collection Specifications represent a list of elements of a particular given type. Individual elements of collections are item Value Specifications. Note that there is no restriction on the item value type of a collection type. This means in particular that a collection type may be parameterized with other collection types allowing collections to be nested arbitrarily deep. Size, uniqueness and order nature of item values are specified by the defining data type.

Constraints

[1] All the item values of a collection are of the same data type

F.13.4 CollectionType (from DataTypes)

Generalizations

- CompositeType (from DataTypes) on page 558

Associations

- collectionAttribute: VSL::DataTypes::Property [1]
attribute that defines the element type, size, uniqueness and order kind of this composite data type.

Semantics

Collection Type describes a list of elements of a particular given type. Part of every collection type is the declaration of the type of its elements by means of the CollectionAttribute. I.e., a collection type is parameterized with an element type. Note that there is no restriction on the element type of a collection type. This means in particular that a collection type may be parameterized with other collection types allowing collections to be nested arbitrarily deep.

F.13.5 CompositeType (from DataTypes)

Generalizations

- DataType (from DataTypes) on page 558

Semantics

Composite types are composed of values, which are made up of values of the owned attributes.

F.13.6 ConditionalExpression (from Expressions)

Generalizations

- Expression (from Expressions) on page 560

Associations

- conditionExpr: VSL::ValueSpecification [1] Boolean expression to be evaluated.
- ifTrueExpr: VSL::ValueSpecification [1] result expression if conditionExpr is evaluated to True.
- ifFalseExpr: VSL::ValueSpecification [1] result expression if conditionExpr is evaluated to false.

Semantics

Conditional Expressions define "if-then-else" statements, which can be used inside an expression. The result of evaluating this expression will be the result of the evaluation of the ifTrueExpr if the conditionExpr is true. Otherwise, the result will be the result of the ifFalseExpr.

F.13.7 DataType (from DataTypes)

DataType matches with the UML concept of DataType. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Generalizations

- Classifier (from Foundations) on page X.

Associations

- ownedAttribute: VSL::DataTypes::Property [*]

Attributes owned by the DataType. This is an ordered collection.

- ownedOperation: VSL::DataTypes::Operation [*]
Operations owned by the DataType. This is an ordered collection.

Semantics

A data type is a special kind of classifier, similar to a class. It differs from a class in that instances of a data type are identified only by their value. All copies of an instance of a data type and any instances of that data type with the same value are considered to be the same instance. Instances of a data type that have attributes (i.e., is a structured data type) are considered to be the same if the structure is the same and the values of the corresponding attributes are the same. If a data type has attributes, then instances of that data type will contain attribute values matching the attributes.

F.13.8 DurationExpression (from TimeExpressions)

Generalizations

- TimeExpression (from TimeExpressions) on page 567

Semantics

DurationExpression is a time expression that denotes a duration value.

F.13.9 DurationIntervalSpecification (from TimeExpressions)

Generalizations

- IntervalSpecification (from CompositeValues) on page 561

Associations

- min : VSL::TimeExpressions::DurationExpression [1] lower duration expression of the Interval.
- max : VSL::TimeExpressions::DurationExpression [1] upper duration expression of the Interval.

Attributes

No additional attributes.

Semantics

Duration Interval Specifications are special kinds of interval specifications that have duration expressions as upper and lower bounds.

F.13.10 EnumerationSpecification (from LiteralValues)

EnumerationSpecification defines the value instance of an enumeration literal.

Generalizations

- ValueSpecification (from VSL) on page 568

Associations

- numLiteral: VSL::DataTypes::EnumerationLiteral [1]referred enumeration literal.

Semantics

EnumerationSpecification defines the value instance of an enumeration literal.

F.13.11 EnumerationType (from DataTypes)

EnumerationType matches with the UML concept of Enumeration. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Associations

- ownedLiteral: EnumerationLiteral [*] set of enumeration literals.

Semantics

The run-tinstances of an Enumeration data type are data values. Each such value corresponds to exactly one Enumeration Literal.

F.13.12 EnumerationLiteral (from DataTypes)

An EnumerationLiteral defines an element of the run-time extension of an enumeration data type.

Semantics

An EnumerationLiteral defines an element of the run-time extension of an enumeration data type. An EnumerationLiteral has a name that can be used to identify it within its enumeration datatype. The enumeration literal name is scoped within and must be unique within its enumeration. The run-time values corresponding to enumeration literals can be compared for equality.

F.13.13 Expression (from Expressions)

Expression matches with the UML concept of Expression. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Generalizations

- ValueSpecification (from VSL) on page 568

Associations

- operand: VSL::ValueSpecification [*] sequence of operands.

Attributes

- symbol: String [0..1] symbol associated with the node in the expression tree.

Semantics

An expression represents a node in an expression tree. If there are no operands, it represents a terminal node. If there are operands, it represents an operator applied to those operands. In either case, there is a symbol associated with the node. The interpretation of this symbol depends on the context of the expression.

F.13.14 ExpressionContext (from Expressions)

Associations

- subContext: ExpressionContext [*]
set of sub-contexts that are used to construct a namespace.

Attributes

- name: String [1] name of the context.

Semantics

Variables are declared in a given Expression Context. The Expression Context's name attribute is used for identification of the variable elements. An Expression Context provides a container for variables. It provides a means for resolving conflicting global variables by allowing Variable Call Expressions of the form ExprContext1::SubContext2::varX.

F.13.15 InstantExpression (from TimeExpressions)

Generalizations

- TimeExpression (from TimeExpressions) on page 567

Semantics

InstantExpression is a time expression that denotes a time instant value.

F.13.16 InstantIntervalSpecification (from TimeExpressions)

Generalizations

- IntervalSpecification (from CompositeValues) on page 561

Associations

- min : InstantExpression [1] lower instant expression of the Interval.
- max : InstantExpression [1] upper instant expression of the Interval.

Attributes

- None

Semantics

Instant Interval Specifications are special kinds of interval specifications that have instant expressions as upper and lower bounds.

F.13.17 IntervalSpecification (from CompositeValues)

Generalizations

- ValueSpecification (from VSL) on page 568

Associations

- min : VSL::ValueSpecification [1] lower value of an Interval.
- max : VSL::ValueSpecification [1] upper value of an Interval.

Attributes

- isLowerOpen: Boolean [0..1] defines if the Interval includes the lower value.
- isUpperOpen: Boolean [0..1] defines if the Interval includes the upper value.

Semantics

An Interval defines the range between two value specifications. The semantics of an Interval is always related to Constraints in which it takes part.

F.13.18 IntervalType (from DataTypes)

Generalizations

- CompositeType (from DataTypes) on page 558

Associations

- intervalAttribute: VSL::DataTypes::Property [1]
attribute defining the bounds part of this composite data type. We use only one property in order to guarantee that the types of both max. and min. bounds are the same.

Semantics

Interval type is a composite data type defining a set of values by means of two bound limits. The minAttribute defines a single value which will designate the lower bound of the Interval. The maxAttribute defines a single value which defines the upper bound of the Interval.

F.13.19 Jitter (from TimeExpressions)

Generalizations

- DurationExpression (from TimeExpressions) on page 559

Semantics

JitterExpression is a duration expression that denotes an unwanted variation (delta) in an event occurrence instant that should occur in periodic intervals.

F.13.20 LiteralSpecification (abstract, from LiteralValues)

LiteralSpecification matches with the UML concept of LiteralSpecification. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Generalizations

- ValueSpecification (from VSL) on page 568

Semantics

A literal specification is an abstract specialization of ValueSpecification that identifies a literal constant being modeled.

F.13.21 LiteralBoolean (from LiteralValues)

LiteralBoolean matches with the UML concept of LiteralBoolean. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Generalizations

- LiteralSpecification (from LiteralValues) on page 562

Attributes

- value : Boolean [0..1] specified Boolean value.

Semantics

A LiteralBoolean specifies a constant Boolean value.

F.13.22 LiteralDateTime (from LiteralValues)

Generalizations

- LiteralSpecification (from LiteralValues) on page 562

Attributes

- value : DateTime [0..1] specified DateTime value.

Semantics

DateTime is a special value used to specify an instant by means of a date and a time in calendar format.

F.13.23 LiteralDefault (from LiteralValues)

Generalizations

- LiteralSpecification (from LiteralValues) on page 562

Semantics

A Default Literal allows specifying a default value. If a default value exists, it is assigned to the value, otherwise the value remains as a Null value.

F.13.24 LiteralInteger (from LiteralValues)

LiteralInteger matches with the UML concept of LiteralInteger. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Generalizations

- LiteralSpecification (from LiteralValues) on page 562

Attributes

- value : Integer [0..1] specified Integer value.

Semantics

A LiteralInteger specifies a constant Integer value.

F.13.25 LiteralNull (from LiteralValues)

LiteralNull matches with the UML concept of LiteralNull. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Generalizations

- LiteralSpecification (from LiteralValues) on page 562

Semantics

LiteralNull is intended to be used to explicitly model the lack of a value.

F.13.26 LiteralReal (from LiteralValues)

Generalizations

- LiteralSpecification (from LiteralValues) on page 562

Attributes

- value : Real [0..1] specified Real value.

Semantics

A value to represent the mathematical concept of a real number. A Real value may be used to specify approximate values that hold continuous quantities, without committing a specific representation such as a floating point data type with restrictions on precision and scale.

F.13.27 LiteralString (from LiteralValues)

LiteralString matches with the UML concept of LiteralString. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Generalizations

- LiteralSpecification (from LiteralValues) on page 562

Attributes

- value: String [0..1] specified String value.

Semantics

A LiteralString specifies a constant String value.

F.13.28 LiteralUnlimitedNatural (from LiteralValues)

LiteralUnlimitedNatural matches with the UML concept of LiteralUnlimitedNatural. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Generalizations

- LiteralSpecification (from LiteralValues) on page 562.

Attributes

- value : UnlimitedNatural [0..1] specified Unlimited Natural value.

Semantics

A LiteralUnlimitedNatural specifies a constant UnlimitedNatural value.

F.13.29 ObservationCallExpression (from Expressions)

Generalizations

- ValueSpecification (from VSL) on page 568

Associations

- observation: VSL::DataTypes::Observation [1]
called Observation.
- conditionExpr: VSL::ValueSpecification [0..1]
condition expression defines an operational (run-time) condition that completes the definition of an observed event.
- occurIndexExpr: VSL::ValueSpecification [0..1]
occurrence index expression that must evaluate to an integer value. The semantic of the occurrence index depends on the observed events. While the absolute order of a given event occurrence regarding other different event could be useful only when both events are synchronized, it exists certain cases where the relative order of an occurrence may be useful to express constraints from different responses of a recurrent scenario.

Semantics

Observation Call Expression refers to a single observation (instant and duration observation). It includes an occurrence index expression (`occurIndexExpr`) that must evaluate to an integer value. Condition expression defines an operational (run-time) condition that completes the definition of a relative event.

F.13.30 OpaqueExpression (from Expressions)

`OpaqueExpression` matches with the UML concept of `OpaqueExpression`. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Attributes

- `body`: String [0..*]
text of the expression, possibly in multiple languages.
- `language`: String [0..*]
set of languages in which the expression is stated. The interpretation of the expression body depends on the languages. If the languages are unspecified, they might be implicit from the expression body or the context. Languages are matched to body strings by order.

Semantics

The expression body may consist of a sequence of text strings - each in a different language - representing alternative representations of the same content. When multiple language strings are provided, the language of each separate string is determined by its corresponding entry in the "language" attribute (by sequence order). The interpretation of the text strings is language specific. Languages are matched to body strings by order. If the languages are unspecified, they might be implicit from the expression bodies or the context.

It is assumed that a linguistic analyzer for the specified languages will evaluate the bodies. The times at which the bodies will be evaluated are not specified.

F.13.31 Operation (from DataTypes)

`Operation` matches with the UML concept of `Operation`. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Associations

- `datatype`: DataType [0..1]
DataType that owns this Property.
- `ownedParameter`: Parameter[*] {ordered}
specifies the parameters owned by this Operation.

Semantics

An operation is invoked on an instance of the data type for which the operation is a feature. The list of owned parameters describes the order, type, and direction of arguments that can be given when the Operation is invoked or which are returned when the Operation terminates.

F.13.32 OperationCallExpression (from Expressions)

Generalizations

- Expression (from Expressions) on page 560

Associations

- definingOperation: VSL::DataTypes::Operation [0..1]
called Operation.
- argument: VSL::ValueSpecification [*] {ordered}
arguments of the Operation Call.

Attributes

- /operation: String [0..1]
string with the name (not qualified name if data types are concerned in the call) of the called Operation. This is a derived value obtained from the defining Operation.

Semantics

An Operation Call Expression refers to an operation defined in a UML Classifier. The expression may contain a list of argument expressions if the operation is defined to have parameters. In this case, the number and types of the arguments must match the parameters.

F.13.33 Parameter (from DataTypes)

Parameter matches with the UML concept of Parameter. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Associations

- operation: VSL::DataTypes::Operation[0..1] operation owning this parameter.

Semantics

A parameter specifies how arguments are passed into or out of an invocation of an operation. The type and multiplicity of a parameter restrict what values can be passed, how many, and whether the values are ordered.

A parameter may be given a name, which then identifies the parameter uniquely within the parameters of the same operation. If it is unnamed, it is distinguished only by its position in the ordered list of parameters.

F.13.34 PrimitiveType (from DataTypes)

PrimitiveType matches with the UML concept of PrimitiveType. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Generalizations

- DataType (from DataTypes) on page 558

Semantics

The run-time instances of a primitive type are data values. The values are in many-to-one correspondence to mathematical elements defined outside of UML (for example, the various integers). Instances of primitive types do not have identity. If two instances have the same representation, then they are indistinguishable.

Additionally, in VSL, a primitive data type may have operations defined through Operation features. The algebra of primitive data types is defined axiomatically outside of UML.

F.13.35 Property (from DataTypes)

Property matches with the UML concept of Property. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Associations

- datatype : VSL::DataTypes::DataType [0..1] the DataType that owns this Property.

Semantics

When a property is owned by a data type via ownedAttribute, then it represents an attribute of the data type. When instantiated a property represents a value or collection of values associated with an instance of one (or in the case of a ternary or higher-order association, more than one) type. The value or collection of values instantiated for a property in an instance of its context conforms to the property's type.

F.13.36 PropertyCallExpression (from Expressions)

Generalizations

- Expression (from Expressions) on page 560

Associations

- definingProperty: VSL::DataTypes::Property [0..1] called Property.

Attributes

- /property: String [0..1]
string with the name (qualified name) of the called Property. This is a derived value obtained from the defining Property.

Semantics

A Property Call Expression is used to refer to Properties in the UML metamodel.

F.13.37 Subtype (from DataTypes)

Generalizations

- DataType (from DataTypes) on page 558

Associations

- `baseType : VSL::DataTypes::DataType [1]` designates an ordered `DataType`.

Semantics

A Subtype is a data type derived from an existing data type, designated the base data type, by restricting the value space to a subset of that to the base data type whilst maintaining all operations.

F.13.38 TimeExpression (from TimeExpressions)

Generalizations

- `ValueSpecification` (from VSL) on page 568

Associations

- `expr: VSL::ValueSpecification [0..1]`
complete time expression containing the usage of the observations given by "obsExpr", other expressions, or whatever value specification.
- `obsExpr: ObsCallExpression [*]`
set of observation call expression that are used in "expr".

Semantics

`TimeExpression` is an expression that factorizes different kinds of time related expressions, including instants, durations and jitters. The Time Expression is given by "expr" which may contain usage of the observations (`obsExpr`) given by `ObsCallExpression`. In the case where there are no "obsExpr", the "expr" will contain a time constant. In the case where there is no "expr", there shall be a single "obsExpr" that indicates the instant or duration expression value.

F.13.39 TupleItemValue (from CompositeValues)

Associations

- `itemValue: VSL::ValueSpecification [1]` value of the item.
- `tupleAttribute: Property [1]` tuple data type's attribute.

Attributes

- `/tupleItemName: String {0..1}` derived String with the name of the tuple data type's attribute.

Semantics

`TupleItemValue` assigns a value specification to instances of the called attributes of a `TupleType`.

F.13.40 TupleSpecification (from CompositeValues)

Generalizations

- `ValueSpecification` (from VSL) on page 568

Associations

- tupleItem : TupleItemValue [*] set of parts of a tuple specification.

Semantics

Tuple Specifications denotes structured values of possibly different types. It contains a name, a type, and a value for each item of the tuple value. There is no restriction on the kind of types that can be used to define item values of tuples. In particular, a Tuple Specification may contain other tuple and collection values.

F.13.41 TupleType (from DataTypes)

Generalizations

- CompositeType (from DataTypes) on page 558

Associations

- tupleAttributes: VSL::DataTypes::Property [*]
attribute defining the type, size, uniqueness and order kind of the structured elements of this composite data type.

Semantics

Tuple Type combines different types into a single composite type. The parts of a Tuple Type are described by its attributes, each having a name and a type. There is no restriction on the kind of types that can be used as part of a tuple. In particular, a Tuple Type may contain other tuple types and collection types. Each attribute of a TupleType represents a single feature of a TupleType. Each part is uniquely identified by its name.

F.13.42 ValueSpecification (abstract, from VSL)

ValueSpecification matches with the UML concept of ValueSpecification. We show below only the associations, attributes and constraints that are relevant for the VSL specification.

Semantics

ValueSpecification is an abstract metaclass used to identify a value or values in a model. It may reference an instance or it may be an expression denoting an instance or instances when evaluated. It is required that the type and number of values is suitable for the context where the value specification is used.

F.13.43 Variable (from Expressions)

Generalizations

- Expression (from Expressions) on page 560

Associations

- datatype: VSL::DataTypes::DataType [0..1]
type of the Variable.
- initExpression: VSL::ValueSpecification [0..1]
initial value specification assigned to the variable when created.

- context: ExpressionContext [0..1]
context of the variable declaration. Expressions making reference to this variable use ExpressionContext's name as namespace.

Attributes

- name: String [0..1]
name of the variable.
- direction: VariableDirectionKind [0..1]
nature of the created variable: input, output, input/output. The complete semantics of this attribute depends on the context on which the variable is created.
- /datatypeName: String [0..1]
string with the name of its DataType. This is a derived value obtained from the associated DataType.

Semantics

Variables are typed elements for passing data in expressions. The variable can be used in expressions where the variable is in scope. Variable creates a variable with a given name, data type, and nature (input, output, input/output).

F.13.44 F.13.44.VariableCallExpression (from Expressions)

Generalizations

- Expression (from Expressions) on page 560

Associations

- definingVariable: Variable [1]called Variable

Attributes

- /variable: String [0..1]
string with the name (containing the ExpressionContext's namespace) of the called Variable. This is a derived value obtained from the defining Variable.

Semantics

Variables are typed elements for passing data in expressions. A variable can be used in expressions where the variable is in scope. A VariableCallExpression is an expression that consists of a reference to a variable.

Annex H: Mapping SPT on MARTE

In order to minimize the impact on users of the SPT profile specification, a precise mapping between the SPT profile and the MARTE metamodels and its defined extensions is provided. Wherever changes have adversely impacted backward compatibility a short rationale has been given. The next table presents the concepts in SPT in the left side and the corresponding elements in MARTE in the right side. The three front-end profile definitions for compliance in SPT has been included, SAprofile, PAprofile, and RSAprofile.

SPT stereotype	MARTE element(s) that may be used to model it in equivalent contexts
SAaction	SaExecStep, SaCommStep, Step
SAengine	SaExecHost, SaCommHost, ProcessingResource, ComputingResource
SAowns	Allocate. This may be also expressed by aggregation between resources
SAPrecedes	PrecedenceRelation. These dependencies are now to be made explicit in the EndToEndFlow by means of the appropriate control nodes.
SAresource	SharedResource, MutualExclusiveResource
SAresponse	BehaviorScenario, SaExecStep
SASchedRes	SchedulableResource
SAScheduler	Scheduler
SAsituation	SaAnalysisContext
SAtrigger	RequestEventStream
SAusedHost	ExecutionStep.concurrentRes association to SchedulableResource
SAuses	SaExecStep.usedResources association to SharedResource
PAClosedLoad	GaWorkloadEvent {pattern = closed(population = XXX:NFP_Integer, extDelay = YYY:NFP_Duration)}
PAcontext	GaAnalysisContext
PAhost	GaExecHost, GaCommHost
PAopenLoad	GaWorkloadEvent {pattern = aperiodic(distribution = XXX)} e.g., exp(YYY:NFP_Duration)
PAresource	Resource (general resource), superclass of these two next: PaRunTInstance (process resource or thread pool PaLogicalResource (other logical resource, eg mutex, buffer, lock)
PAscenario	GaScenario

PAstep	PaStep
PAperfValue	NFP, including VSL for values
PAextOpValue	extOpDemand, extOpCount pair for service and frequency
RSACHannel	SaCommunicationHost
RSAClient	This has not a direct mapping, but it can be represented with an RtUnit or a structured class having the SchedulableResource, the behaviors of the client, the CommunicationChannel to the server, and the ResourceBroker.
RSACONNECTION	This has not a direct mapping, but it can be represented with a Share-dResource and a CommunicationChannel.
RSAMutex	MutualExclusiveResource, PpUnit
RSAAORB	This does not have a direct mapping, but it can be represented using a SecondaryScheduler, RtUnit, and MutualExclusiveResources.
RSAServer	This does not have a direct mapping, but it can be represented using an RtUnit or a structured class having the SchedulableResource, the behaviors of the client, and eventually the SecondaryScheduler.
